NEUROANESTHESIA CRISIS MANUAL

Angela Builes

Edited by:

Miguel Arango
Luis Fernando Botero
The purpose of this crisis manual is to be a resource for anesthesiologists and to prepare them for stressful situations that may arise during neurosurgical procedures. It is meant to be a reference only and a cognitive aid in emergency situations. It is NOT a guideline or a protocol that anesthesiologists are obligated to follow. This manual may provide a vehicle for input and practical strategies when facing critical events with neurosurgical patients.

We based the content on our literature review, accepted guidelines, algorithms, academic resources and by experiences learned in practice.

This manual introduces our mental model and decision-making frame. It provides methods to manage these emergencies, especially when treatment requires multiple tasks performed simultaneously by different individuals.

The manual will provide a team with a checklist of the tasks that need to be completed.

**Limitations:**

During our literature review, we focused on an adult population. However, most of the principles apply to pediatric cases with appropriate considerations (including doses) adjusted for this population.

**Recommendation:**

Implementation and management of emergency situations can vary according to institutions, regulations, team compositions, or updated evidence. We suggest the readers adapt within their own organization and discuss with the neurosurgical teams. This manual should be a living document. As future evidence changes procedure, an update of the manual will be necessary. Once you reach consensus start implementing your own manuals in your neurosurgical operating rooms using simulation-based training.

For more information on how to implement Emergency Manuals check: https://www.implementingemergencychecklists.org
How to use the NeuroAnesthesia Crisis Manual?
When using the manual, we recommend delegating one person to verify that important steps are not missed when following this guide.

Two pages will be used to cover each crisis. The first will include information about the patient at risk, the prevention strategies that could be implemented and the signs, symptoms, and differential diagnosis for each one. The second page is devoted to the treatments actually performed.

Note: The author and editors disclaim all liability from the use of the material, each clinician is responsible for the interpretation and use of the manual in the clinical setting.

We dedicate The Neuroanesthesia Crisis Manual to the patients that give us their trust daily.

1. ACCIDENTAL EXTUBATION IN PRONE POSITION

**Signs**

Drop or complete loss of EtCO₂
Gas reservoir of machine empty
Machine does not deliver adequate inspiration tidal volumes, maximal leakage

**Special Consideration**

Critical moments of neurosurgery require deep anesthesia and neuromuscular blockade.
AVOID valsalva maneuvers

**Initial Assessment**

Switch to MANUAL/ BAG ventilation
Increase FiO₂ to 100%
Increase fresh gas flow to maximum
Consider use of oxygen- “flush” button for maximum flow
Test to see if manual (bag) ventilation is possible
Feel resistance during manual ventilation. If no resistance: significant problem

CHECK circuit for leaks:
- Connections to the anesthesia machine
- Connections to the endotracheal tube
- Listen for leaks

**When Preparing to Turn a Patient Ask Neurosurgeon to:**

Flood surgical field with saline
Remove surgical Instruments
Pack the wound with a saline soaked swab
Cover the wound with adhesive dressing
Release clamp
Hold the head in neutral position
1. ACCIDENTAL EXTUBATION IN PRONE POSITION

Treatment

**Complete Extubation**
- Announce EMERGENCY to the team
- Ask for HELP
- Ask for Difficult Intubation Cart
- **Stop Procedure**
- Notify Neurosurgeon: prepare for turning
- Ask for a stretcher
- Increase Oxygen flow to 100% FiO₂

Immediate oxygenation/ventilation options in Prone:
- Insert a Supraglottic Airway Device (2nd generation/intubating supraglottic airways are preferred)
- Attempt bag mask ventilation in prone with high-flow, 100% FiO₂, consider use of nasal/oral airway

(If oxygenation is easy to maintain, consider one intubation attempt in prone position. Consider use of flexible intubation endoscope / video laryngoscope (if provider is highly skilled and if the approach is feasible))

**Prepare for turning**
- Secure IV access
- Airway management in Supine Position

**Partial Extubation** (Diagnosed by: depth of tube, capnography, ventilation parameters, presence of leak)
- Increase fresh gas flows and FiO₂ to 100%

- Advance endotracheal tube (through Bougie or Endotracheal Tube Catheter, consider use of flexible intubation endoscope) in prone position

- Check for correct tube position

- If adequate ventilation and endotracheal intubation is achieved, announce that situation is safe and continue surgery

- If ventilation and intubation is not achieved:
  - **Prepare for turning**
  - Maintain oxygenation via: endotracheal tube or supraglottic airway device (2nd generation/intubating supraglottic airways are preferred) or bag mask ventilation in prone position (consider use of oral/nasal airway)
  - **Turn to supine position**
  - Airway management in supine position
2. DECISION MAKING AFTER PROLONGED PRONE POSITION FOR EXTUBATION

Risk Factors

**Surgery associated risks:** surgery > 6 hours, ↑ blood loss, ↑ IV fluid, C-spine surgery  
**Patient associated risks:** Age > 70 yrs, obesity, obstructive, sleep apnea, chronic obstructive pulmonary disease, rheumatoid arthritis, hemoglobin < 10 mg/dl, difficult airway, neuromuscular disease, malnutrition, hypoalbuminemia

Prevention

Consider colloids over crystalloids for fluid resuscitation  
Cuff pressure measurements during procedure, aim for < 20 cm H₂O  
Avoid Extreme Neck Flexion

Airway Edema Assessment Options

Laryngoscopic assessment of pharynx/larynx (prefer video laryngoscope with hyperangulated blade, look for evidence of edema)  
Cuff Leak Test  
Airway Ultrasound  
Sufficient reflexes (cough, gag, and swallow)  
Physical examination:  
  - Neurologic status (Coma Recovery Scale-Revised Visual Subscale)  
  - Inspection of neck, eyes, and tongue for edema

Extubation Criteria

**Patient conditions**  
No signs of airway edema / obstruction  
Slow emerge from anesthesia, consider using Remifentanil iv infusion to allow tube tolerance  
Sufficient spontaneous ventilation with adequate, regular respiratory efforts  
Hemodynamic and metabolically stable  
Sufficient protective reflexes (gag, swallow, cough)  
Reversal of neuromuscular blockade (TOF > 90%)  
Normothermia

**Other**  
Adequate location for extubation (monitoring, difficult airway equipment readily available)  
Help and skilled personnel available
2. DECISION MAKING AFTER PROLONGED PRONE POSITION FOR EXTUBATION

**PLAN**
Assessment of: Airway, patient’s condition, extubation potentially successful, equipment and skilled personnel

**PREPARE**
Optimize patient and other factors (equipment, personal, location)
Suction secretions without trauma

**Is Patient Safe to Extubate?**
- **Yes**
  - Options:
    1. Remifentanil technique
    2. Exchange Catheter
- **No**
  - Postpone extubation
  - Transfer to ICU
  - Consider Tracheostomy

**PERFORM EXTUBATION**

**POSTEXTUBATION CARE**
Comprehensive documentation and handover
Monitoring and care by skilled / qualified personnel
Advanced airway management equipment readily available
3. NEUROGENIC PULMONARY EDEMA

Risk Factors

**Acute Cerebral or Cervical Spine Cord Insult:**
- Aneurysmal subarachnoid hemorrhage
- Traumatic brain injury/cervical injury
- Intracranial hemorrhage
- Intracranial tumours
- Seizures
- Postoperative intracranial surgery
- Meningitis

Signs

Central Neurologic Injury + Sudden Dyspnea

Other signs:
- Tachypnea
- Tachycardia
- Pulmonary crackles and rales on auscultation, "B" lines in lung US
- Cyanosis
- Pink frothy sputum
- Respiratory failure

Assessment

Arterial blood gases: \( \downarrow \text{PaO}_2 / \text{FiO}_2 < 200 \)

X-Ray: Bilateral infiltrates

**Point of Care Ultrasound:**
- **Cardiac US:** Assessment of left ventricular function
- **Lung US:** B-lines
- **Inferior Vena Cava** measurement

EKG: Ischemia findings

Differential Diagnosis

- Cardiogenic Pulmonary Edema
- Aspiration Pneumonia
- Ventilator Associated Pneumonia
- Ventilator Induced Lung Injury
- Transfusion Related Acute Lung Injury
- Sepsis
- Pneumothorax
### 3. NEUROGENIC PULMONARY EDEMA

#### Treatment

1. **Oxygenation:**
   \[ \text{↑ FiO}_2 \]
   - Mechanical or Non-Invasive Ventilation if no contraindications
   - (Keep PEEP \(< 15 \text{ cm } H_2O\) / avoid AutoPEEP)
   - Request the ICU Ventilator if needed
   - Use a muscle relaxant agent if needed

2. **Treat primary brain injury-associated intracranial hypertension** (examples):
   - Decrease ICP (if it has increased, see crisis #8 page 22 Intracranial Hypertension)
   - Evacuate hematoma
   - Treat seizures
   - Acute hydrocephalus: External ventricular drain

3. **Avoid increase in intracranial pressure:**
   - Ensure adequate anesthesia depth according to surgical procedure
   - Avoid bronchoscopy unless absolutely necessary

4. **Maintain adequate cerebral perfusion:**
   - **Hemodynamic support:** Phenylephrine, Norepinephrine infusions
   - Avoid hypotension, goal MAP \(≥ 70 \text{ mm Hg}\)
   - Caution with therapies: diuretics and high PEEP
   - Maintain hemoglobin \(> 10 \text{ g/dl}\)
   - Maintain normocapnia
   - Maintain normal temperature

5. **Monitor patient’s intravascular volume status and fluid responsiveness to guide fluid management in the setting of pulmonary edema:**
   - Pulse wave pressure variability \(< 13\)
   - Focused cardiac US:
     - IVC Distensibility index \(< 18\%\), \(< 3 \text{ B-lines in each lung region}\)
     - LVEF visual assessment normal or increased

6. **Circulation:** Consider Dobutamine and inotropes if necessary

7. **Other Options:**
   - **Diuretics:** Furosemide
   - **Corticosteroids** (Brain tumors/Multiple Sclerosis) **NOT IN TRAUMATIC BRAIN INJURY**
   - Beta and alpha adrenergic blockers, according to hemodynamic profile

8. **Transfer to ICU**
   - Considerations for Brain-Dead Organ Donors:
     - **Nitric Oxide (NO)** if pulmonary hypertension is suspected
     - **ECMO**
4. CARDIAC ARREST IN PRONE POSITION

Reversible Causes

Air Embolism (see crisis #5 Air Embolism, page 16)
Parasympathetic Reflex - Surgical Stimulation
Sudden Increase in ICP (see crisis #8 intracranial hypertension page 22)
Prone Position
Intracranial Hypotension (Check Drains, see crisis #10 intracranial hypotension page 26)
Medications (Dexmedetomidine, Remifentanil, Phenytoin, Beta-blockers)
Local Anesthesia Toxicity
Spinal Shock
Anaphylaxis
Auto-PEEP
Brain Irrigation with Warm (42 °C) or Cold (20 °C) Saline

Hypovolemia
Hypoxia
Hydrogen (Acidosis)
Hypo/Hyperkalemia
Hypo/Hyperthermia
Hypoglycemia

Tension Pneumothorax,
Tamponade, Cardiac
Toxins
Thrombosis, Pulmonary
Thrombosis, Coronary
Tension Pneumocephalus

Effectiveness of CPR

Start reverse CPR compressions (see figures): Perform sterile CPR as soon possible
Guide compressions
EtCO₂ > 20 mmHg
Arterial line diastolic blood pressure > 40 mmHg
Push chest at least 5 cm
Allow recoil
Rotate person compressing the chest

Defibrillation on Prone:
Pads on Postero-lateral (left mid axillary line + right scapula)
or bi-axillary position
4. CARDIAC ARREST IN PRONE POSITION

Treatment

**Confirm Cardiac Arrest** (Pulse-Monitors)

**Activate Code Blue** (Ask for HELP - Crash Cart - a Stretcher and Board for Support)

Ask Surgeon to **STOP PROCEDURE**

Start Effective CPR in Prone

(Compressions at least 100-120 mmHg

Ventilation 10 pm)

Minimize Interruptions

Check Rhythm and pulse/ 2 min

Check Rhythm

<table>

5. AIR EMBOLISM

Patients at Risk

Surgical field above heart level: sitting, lateral, prone
Posterior fossa procedures
Deep brain stimulator procedures
Cervical laminectomy
Craniosynostosis
Posterior spinal fusion
Hypovolemia
Spontaneous ventilation
Hydrogen peroxide for wound irrigation
Use of NO$_2$

Prevention

Look for PFO (TEE)
Good care of IV lines
Euvolemia
Adequate irrigation
Use of waxing

Signs and Symptoms

5. AIR EMBOLISM

Treatment

Announce EMERGENCY to the team

Ask Neurosurgeon to **STOP PROCEDURE**

**Ask for Help**- Crash Cart

**Change position** to Trendelenburg (tilt left side)

↑ FIO₂ to 100%

Administer bolus of IV fluids

Stop NO₂ (if used)

Ask the Neurosurgeon to:
- **Flood** the wound with saline
- **Wax** bone edges
- **Cover exposed areas** with large pieces of wet sterile sponges

Verify that there is no AIR in IV lines

**RAPID ASPIRATION THROUGH CENTRAL LINE**

Start vasopressors (if hypotension)

Compression of both Jugular veins

If patient has cardiac arrest, start CPR (see crisis # 4 Cardiac Arrest Prone Position, page 14)

Consider TEE for monitoring (other monitors: precordial Doppler, TTE)

Consider hyperbaric oxygen therapy (in case of cerebral arterial gas embolism)

Keep hemodynamic and ventilator support, if necessary

Transfer to ICU
6. ANEURYSM RUPTURE DURING CLIPPING

Risk Factors

Hypertension (history or presented with high blood pressure)
Recent rupture
Smoking history
Large size

Prevention

**Before surgery:**
- Reserve FFP, red blood cells
- Apply pads
- Reserve ICU
- Double suction setting
- Adenosine available in the OR
- Have crystalloids with pressure bag ready
- Use Neuromonitoring if possible (BIS, NIRS, Evoked Potentials), when applicable

**During surgery:**
- Use osmotic therapy to optimize surgical access
- Adequate use of neuromuscular agents when transferring intubated patients
- At the moment of Durotomy, keep MAP 20% below baseline (Avoid big changes in transmural tension)

Avoid

**Sympathetic responses:** intubation
**Abrupt changes in ICP:** coughing, gagging, hypotension, hyperventilation
**Excessive drainage of CSF:** large dose Mannitol, valsalva
**Hypertension** at the moment of Durotomy

Signs

**Sudden changes without other explanation**

**Clinical:** hypertension, bradycardia, arrhythmias, and blown pupil

**Surgical:** evidence of bleeding, brain bulge

**Monitors:** Suddenly increased intracranial pressure (ICP), sudden unexplained changes on the monitors
6. ANEURYSM RUPTURE DURING CLIPPING

**Treatment**

Announce EMERGENCY to the team

Continue to communicate with the Neurosurgeon
  - Suggest the most senior surgeon in the room to take over
  - Verify double suction setting
  - Suggest using cotton to suppress bleeding

↑ $\text{FiO}_2$ to 100%

Request red blood cells to blood bank

**Management of MAP** (Goal 60 to 80 mmHg)

Controlled decrease of MAP (SHORT PERIOD OF TIME) (for approx. 3 minutes)
  - Propofol 1 - 2 mg/kg or
  - Thiopental 5 - 10 mg/kg or
  - Esmolol 1 mg/kg or
  - Labetalol 10 mg IV initially, then 20 mg IV q10min; do not to exceed 300 mg

↓ Cerebral metabolic rate: (propofol 1 - 2 mg/kg or Thiopental 5 - 10 mg/kg)

Keep intravascular volume: crystalloids, transfusion if applicable

Sustain hemodynamic changes with vasopressors, titrate accordingly

**Efforts to Stop Bleeding:**
  - Temporary clip
  - Compression of ipsilateral Carotid Artery (for Anterior Circulation Aneurysms)
  - Cardiac Arrest
    - Adenosine 1$^{\text{st}}$ dose: 6 mg, 2$^{\text{nd}}$ dose: 12 mg
    - Rapid ventricular pacing

Consider seizure prophylaxis Levetiracetam 20 mg/kg in 100 cc NaCl 0.9% in >15 minutes or Phenytoin: 20 mg/kg in 30 min. Start EEG

Ventilation and hemodynamic support
Transfer to ICU
7. ANEURYSM RUPTURE DURING COILING

Patients at Risk
Hypertension (history or presented with high blood pressure)
Recent rupture
Small aneurysms
Presence of smaller associated aneurysm
Past medical history: COPD, coronary artery disease/smoker/hyperlipidemia

Avoid

**Sympathetic Responses:** Intubation
**Abrupt changes in ICP:** Coughing/gagging/hypotension/hyperventilation
Caution with osmotic therapy
**Suddenly decrease in brain parenchyma volume (↓ICP):** large dose Mannitol

Signs

**(Sudden changes no explanation)**

**Clinical:** hypertension, bradycardia, arrhythmias, blown pupil

**Radiographic:** dye extravasation, prolongation of contrast dye transit time, mechanical perforation, diversion of blood flow

**Monitors:** sudden increase ICP, sudden changes in monitors
### Treatment

Announce EMERGENCY to the team  
Ask for Help (CT-Scan-Neurosurgeon-request OR available)

↑ **FIo₂** to 100%

Request red blood cells to blood bank and platelets if needed

**Management of MAP** (Goal 60 to 80 mmHg)
- *Propofol* 1 - 2 mg/kg or  
- *Thiopental* 5 - 10 mg/kg or  
- *Esmolol* 1 mg/kg or  
- *Labetalol* 10 mg IV initially, then 20 mg IV q10min; do not to exceed 300 mg

↓ **Cerebral metabolic rate:** (Propofol 1 - 2 mg/kg or Thiopental 5 - 10 mg/kg)

**Management of ICP**

- **No Signs of Herniation:**  
  Avoid hyperventilation if there is hypotension
  Once the rupture is solved, start management of ICP  
  *(see Crisis #8, page 22)*

- **Signs of Herniation:**  
  Manage ↑ ICP  
  *(see Crisis #8 Intracranial Hypertension, page 22)*

**Prompt Reverse heparin:** get ACT or consider time since last dose of Heparin.  
(Protamine Sulfate 1 mg for each 100 units of Heparin given)

Continue to communicate with the Neurosurgeon:  
**Endovascular treatment:** Partial or complete packing of aneurysmal sack with Coils is feasible? embolization to seal?

**Surgical treatment:** Ventriculostomy or emergent Craniotomy and Clipping or Decompressive Hemicraniectomy  
**Prepare for surgery:** get ACT, get **CT-Scan**, prepare for transport, consider ventriculostomy catheter: drain at 15-20 cm H₂O above Tragus

**Consider seizure prophylaxis:** Levetiracetam 20 mg/kg in 100 cc NaCl 0.9% in >15 minutes or Phenytointin: 20 mg/kg in 30 min. **Start EEG**

Ventilation and hemodynamic support  
Transfer to ICU or Operating Room
## 8. INTRACRANIAL HYPERTENSION

### Patients at Risk
- Severe Traumatic Brain Injury
- Hemispheric Stroke
- Intracranial Hemorrhage
- Severe Intracranial Hypertension
- Acute Hydrocephalus
- Meningitis

### Signs

**Intracranial Pressure** >20 mmHg (>5min) if Measured

**Signs of Herniation:**
- Hypertension, bradycardia, irregular respirations or apnea
- Pupillary dilation

**Loss of Brainstem Reflexes:**
- Blinking, gagging, pupils reacting to light,
- Loss consciousness
- Respiratory depression
- Dysrhythmias
- Cardiac arrest
## 8. INTRACRANIAL HYPERTENSION

### Treatment

#### Physiologic therapies
- **Head elevation:** 20 - 30°
- **Neutral neck positioning** to ensure venous drainage
- **Hyperventilation (as a bridging therapy):**
  - (\(\text{PaCO}_2\) 30-35) short time (5 - 10 min without hypotension)
  - ↑\(\text{FiO}_2\) to 100%
- **Keep adequate blood pressure:** MAP 90-110 mmhg
- **Decrease intrathoracic pressure** (low PEEP)
- **Keep temperature control** (normothermia)
- **Check normoglycemia** (80-150 mg/dl)
- **Minimize tracheal suctioning**
- **Measure electrolytes and arterial gases.**

#### Avoid valsalva maneuvers:
- Maintain **deep anesthesia** and/or use **muscle relaxant agent.**

#### Pharmacologic treatment
- **Mannitol** 0.5-1 g/kg
- **Hypertonic Saline over 20 min:** (NaCl 3% 3 mL/kg or NaCl 7.5% 2 mL/Kg)
- **Furosemide** 10 to 20 mg
- **Propofol** Bolus 1-2 mg/kg  OR  
- **Thiopental** 5-10 mg/kg initial dose
- **Anesthesia inhaled agents** MAC < 1, if it is not improving, **CHANGE FOR TIVA**
- Consider **Dexamethasone** (if vasogenic edema is suspected)

#### Consider EEG monitoring
- and decide the use of:
  - **Phenytoin** 20 mg/kg in 30 min initial dose  OR
  - **Pentobarbital** 10mg/kg over 30 min then 5 mg/kg/h x 3 h then 1-4 mg/kg/h
  - or **levetiracetam** 20 mg/kg 100 cc NaCl 0.9% in >15 minutes

#### CT-SCAN
- Consider: ventricular drainage, Decompressive Craniotomy
- Start deep sedation and consider additional monitoring (NIRS, EEG, TCD)
- Keep ventilation and hemodynamic support
- Transfer to ICU
9. DELAYED AWAKENING

Risk Factors

**Surgical associated risks**
- Frontal brain resection
- Posterior fossa
- Tumor size > 30 mm
- Midline shift > 3 mm
- Cerebral edema
- Proximity to the Ascending Reticular Activating System
- Temporary occlusion of arteries
- Hematoma exceeding 2-3 cms
- Neuroendoscopic procedure
- Transsphenoidal surgery with use of Oxymetazoline
- Hypothermia

**Patient associated risks**
- Epileptic patients
- Parkinson Disease
- Obese
- Elderly
- Porphyria
- Mucopolysaccharide Disease
- Hypothyroidism
- Renal failure
- Liver failure

**Medications**
- Narcotics
- Muscle relaxants
- Toxins (Alcohol, etc)
- Antiepileptic medications
- Anticholinergic agents
- Nasal Oxymetazoline
- Benzodiazepines
- Barbituric agents
- Anti-epileptic agents (AEA)
- Parkinson medications
- Dexmedetomidine
- Haloperidol
9. DELAYED AWAKENING

Verify

Vital signs (ABCD)
All anesthetic agents and opioids are stopped
TOF >90%
Check: Pupils, lateralizing signs
Check: Blood gases (Na, K, Ph, P$_a$CO$_2$) and glucometry, temperature, Mg++, Ca+, BUN
Check: Amount of CSF drainage
Review medications

Treatment

**Consider:**
Opioid reversal: **Naloxone** 40 mcg IV and repeat every 2 minutes Up to 2 mg
Benzodiazepines reversal: **Flumazenil** 0.1 mg IV q 2 min until 1 mg
Anticholinergic medications: **Physostigmine** 1 mg (rate 1mg/min)

**EMERGENT CT-SCAN**
Don’t extubate
Inform Neurosurgeon – Consult Neurology if necessary
Consider brain monitors: BIS, NIRS TCD, accordingly

**Differential Diagnosis**
- Hypoglycemia: give Dextrose 50% 50 cc IV
- Hypothermia: start re-warming
- Cerebral ischemia/stroke: MRI, hemodynamic support, consult Neurology
- Vasospasm: Request TCD
- Cerebral hemorrhage: CT-Scan and discuss with Neurosurgery according to findings
- Tension Pneumocephalus: Emergent surgical intervention
- Rupture Aneurysm: CT-Scan and discuss with Neurosurgery according to findings
- Seizure Disorder: Start EEG
- Cerebral Hypotension (Trendelemburg positioning, (see Crisis #10 Intracranial Hypotension, page 26)

Continue ventilation and hemodynamic support
Transfer to ICU
## 10. POSTOPERATIVE INTRACRANIAL HYPOTENSION

### Patients at Risk
- Brain or spine trauma
- Spine surgery
- VP shunts
- Postoperative drainage of brain hematoma
- Any Craniotomy
- Intraoperative drainage of CSF

### Signs
- Delayed recovery from anesthesia
- Mydriasis and non-reactive **BILATERAL pupils**
- Absence of decerebration and decortication reflexes
# 10. POSTOPERATIVE INTRACRANIAL HYPOTENSION

<table>

## 11. POSTOPERATIVE SEIZURES

**Patients at Risk**

**Metabolic:** hypoglycemia, hypocalcemia, hypophosphatemia, hyponatremia, uremia

**Drug Withdrawal:** Alcohol, barbiturics, benzodiazepines, opioids

**Brain Injury:** Traumatic brain injury, stroke, subarachnoid hemorrhage, intracranial hemorrhage, infections

**Brain surgery:** Glyomas, cortical stimulation, brain tumours, surgery in motor cortex

**Others:** **ANTIEPILEPTIC DRUG (AED) WITHDRAWAL**, younger age, hyperventilation, changes in AED, pain, stress, fever, infection, local anesthetic toxicity
11. POSTOPERATIVE SEIZURES

**SUPPORTIVE MEASUREMENTS**

**Airway:** Secure and support

**Monitors:** Respiratory, cardiac, temperature, EEG

**IV:** Secure IV access and drop blood samples for: Blood gases, Na, Ca, Mg, PO₄, BUN, AED levels, alcohol, toxic panel

**Glucometer:** if < 60 mg/dl, 50 ml Dextrose 50%, consider Thiamine 250 mg, for Alcohol Consumption or impaired nutrition

**Oxygen and Observe:** Maintain oxygenation and perform neurologic exam

**0-5 minutes**

**FIRST 5 minutes**

**5 – 20 minutes**

**Check exams and treat reversible causes**

**ASK FOR HELP!**

**BENZODIAZEPINE TRIAL**

- Lorazepam: 0.1 mg/kg max 4 mg Repeat Once or
- Midazolam: 5 mg IV or IM, Intranasal, Buccal (2.5 mg for fragile, elderly or severe comorbidities) or
- Diazepam: 0.15-0.2 g/kg max 10 mg/dose

**ANTI EPILEPTIC DRUG (AED)**

- Levetiracetam: 20 mg/kg in 100 cc NaCl 0.9% in >15 minutes or
- Phenytoin: 20 mg/kg in 30 min or
- Phenobarbital: 20 mg/kg in 30 min

**STAT 20 MINUTES EEG**

**If Seizures Continue After 20 minutes**

**GENERAL ANESTHESIA**

- Prepare for RSI
- Propofol Infusion

**EMERGENT CT-SCAN**

Ventilation and hemodynamic support
Transfer to ICU
Continue AED infusions, consider continuous EEG

Call Neurologist or epileptic clinic consult
## 12. INTRAOPERATIVE SEIZURES

### Risk Factors

**Patient associated risks:**
- History of seizures
- Preoperative seizures
- Young patients
- Uncontrolled diabetes
- Hyponatremia

**Surgery associated risks:**
- Grade ii gliomas
- Frontal lobe surgery

**Moment in surgery:**
- Brain mapping
- Tumour resection
- Cortical stimulation

**Withdraw of Anti-Epileptic Drugs**

### Avoid:

- Etomidate
- Ketamine
- Hyperventilation
- Flumazenil
12. INTRAOPERATIVE SEIZURES

Treatment

Announce EMERGENCY to the team

Ask the surgeon to stop cortical stimulation

Irrigate cold saline on the brain or surgical field

If seizures stopped, continue procedure.

If seizures don’t stop:

Basic support measurements:
- Patent airway
- Assist ventilation
- Cardiovascular stability

Medications:
- Propofol: 0.5 mg/kg
- Midazolam: 1 or 2 mg bolus

Talk to neurosurgeon and neurophysiologist:

Assess if you can continue with micro or macro recording. (If it is safe, continue with the procedure)

If seizures recurred, ABORT PROCEDURE

Remove head from frame and pins

Repeat Midazolam: 1 or 2 mg
Start Levetiracetam 20 mg/kg in 100 cc NaCl 0.9% In >15 minutes or
Phenytoin: 20 mg/kg in 30 min

Continue seizures management (see crisis #11 Postoperative Seizures, page 28)
### 13. INTRAOPERATIVE STROKE

#### Risk Factors

**Patients associated risks:**
- Atrial fibrillation
- Elderly (>65 y/o)
- MI (<6 months)
- Acute renal failure
- Smoker
- Cardiac valve disease
- Previous stroke (<9 months)
- History of brain radiotherapy

**Procedure:**
- Carotid endarterectomy
- Carotid stent
- Aneurysm clipping or coiling
- Intraoperative hypotension

**Neck surgery:**
- Neck rotation and extension
- Arthritis cervical spine
- Tumors involving Carotid Artery
- Intraoperative hypotension
- Patient sitting position

#### Signs

<table>
<thead>
<tr>
<th>Awake Patient:</th>
<th>Patient under General Anesthesia:</th>
<th>Emergency from general anesthesia:</th>
</tr>
</thead>
<tbody>
<tr>
<td>New neurologic deficit</td>
<td>Changes in neuromonitors NIRS (drop &gt;20%), Unexpected changes in TCD or SSEP Angiographic evidence of new bleeding or thrombosis Unexplained hemodynamic changes</td>
<td>New neurologic deficit Delayed awakening (see crisis #9 delayed Awakening, page 24)</td>
</tr>
</tbody>
</table>
13. INTRAOPERATIVE STROKE

**Treatment**

Announce EMERGENCY to the team  
If it is possible, STOP procedure  
Talk to the Neurosurgeon  
Activate Stroke protocol (If available)  
Allocate one person to assess neuro-status: NIHHS score and record time  
**Maintain:**  
Hemodynamics (ABCD, intubate if needed*)  
*Intubate if: GCS ≤ 8, agitation, decline of Level of consciousness, vomiting, respiratory failure  
Normal glucose level (80-150 mg/dl)  
Normal level of P$_{2}$CO$_{2}$  
Normal temperature  
Normal oximetry > 94%  
Hemoglobin levels > 10g/dl  
Adequate oxygenation  
Get an ACT if Heparin has been used  
Get stat labs: INR/PTT, CBC, Fibrinogen  

Perform an EMERGENT CT-SCAN or Angiography (or dMRI) according to situation  

**Ischemic Stroke:**  
- Increase MAP, do not exceed < 185/110. AVOID HYPOTENSION!  
- Consider stent  
- Mechanic or pharmacologic thrombolysis  
- Discuss with surgeon options: Abciximab or intra-arterial Vasodilators  
- Consider Aspirin 81 mg/d and Clopidogrel 75mg/d, statins according to situation  

**Hemorrhagic Stroke:**  
- Decrease MAP, maintain Systolic Blood pressure < 140-150 mmHg  
- Elevate head 30 degrees  
- Reverse Heparin (Per ACT) with: Protamine 1 mg for every 100 IU of Heparin  
- Consider transfusing platelets in those with Aspirin and Clopidogrel  
- Consider cryoprecipitate (6-8 units)  
- Discuss with the surgeon: attempt of Coil or Balloon Occlusion on site of hemorrhage  

**Other considerations:**  
- Obtain a 12-lead ECG  
- Perform a point of care ultrasound: Carotid imaging, left ventricle assessment  
Keep adequate oxygenation and hemodynamic support  
Transfer to ICU
14. HYponatremia: Cerebral/renal Salt Wasting Syndrome

Patients at Risk

- Subarachnoid hemorrhage
- Traumatic brain injury
- Brain tumors
- Brain infarction
- Intracranial hemorrhage
- Arteriovenous malformation
- Meningitis
- Intracranial surgery

Diagnosis

**Hyponatremia** (plasma levels of Na+ < 135 mEq/L)

**Hypovolemia** (tachycardia, hypotension, thirst, dry mucous membranes, ↓ CVP)

**Hypo-osmolality** (Plasma osmolality < 275 mOsm/Kg)

- Urinary Na+ > 40 mMol/L
- Fractional excretion of urate after correction: high

Classification of Hyponatremia

<table>
<thead>
<tr>
<th>Plasma Levels of Na⁺ (mEq/L)</th>
<th>Mild: Na⁺ 130-135</th>
<th>Moderate: Na⁺ 125-129</th>
<th>Severe: Na⁺ &lt; 125</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symptoms</td>
<td>Moderate-chronic: nauseas, fatigue, gait and attention deficit, falls. Severe acute: vomiting, headache, seizures, coma, death, respiratory arrest, neurogenic pulmonary edema, brain herniation</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Time</td>
<td>Acute &lt; 48 hours</td>
<td>Chronic &gt; 48 hours</td>
<td></td>
</tr>
</tbody>
</table>

Differential Diagnosis

- Diuretics
- Osmotic therapy
- Hyperglycemia
- Media contrast diuresis
- Addison's disease
**14. HYPONATREMIA: CEREBRAL/RENAL SALT WASTING SYNDROME**

**Treatment**

Draw blood sample: repeat electrolytes, glucose levels, uric acid

Measure urine osmolality, density and Na+, uric acid

Treat HYPOVOLEMIA first: Hydrate patient with NaCl 0.9 % (*Normal Saline*)

If **severe and/or acute hyponatremia**:  

**NaCl 3% 100 cc IV bolus** over 20 minutes  
Repeat Maximum 2 more times if the rise in Plasma Na+ ≤ 5 mEq/L  

**Aims of Na⁺ Correction:**  
↑ 3-5 mEq/L over first 2-4 hours  
↑ 6-8 mEq/L over 24 hours  
**LIMITS** ↑ 10 mEq/L 24 hours (8 mEq/L in patients with hypokalemia, alcoholism, malnutrition, liver disease)

Repeat plasma levels of Na⁺ every 2 hours until Na⁺ stabilized, then every 6 hours  

Monitor volume status and treat hypovolemia, fluids and urinary output  

Treat underlying cause, if possible  

Refractory cases: **Fludrocortisone 0.1-0.2 Mg** orally twice a day  

If patient awake: oral salt supplementation
15. HYPONATREMIA: SYNDROME OF INAPPROPRIATE ANTIDIURESIS (SIAD)

**Patients at Risk**

<table>
<thead>
<tr>
<th>Patients at risk</th>

<td>Chronic &gt; 48 hours</td>
<td></td>
</tr>
</tbody>
</table>

**Differential Diagnosis**

Heart, liver or kidney failure
15. HYponatremia: Syndrome of Inappropriate Antidiuresis (SIAD)

**Treatment**

Draw blood sample: repeat electrolytes, glucose levels, uric acid

Measure urine osmolality, density and Na+, uric acid

Fluid restriction: 500 cc below average daily urine volume

If **severe and/or acute hyponatremia**:

- **NaCl 3% 100 cc IV bolus** over 20 minutes
  - Repeat for a maximum of 2 more times if the rise in plasma is Plasma Na+ < 5 mEq/L

  **Aims of Na+ Correction:**
  - ↑ 3-5 mEq/L over first 2-4 hours
  - ↑ 6-8 mEq/L over 24 hours
  - LIMITS ↑ 10 mEq/L 24 hours (8 mEq/L in patients with hypokalemia, alcoholism, malnutrition, liver disease)

Repeat plasma levels of Na+ every 2 hours until Na+ stabilized, then every 6 hours

Eliminate reversible causes: (stop medications that increase risk)

Monitor volume status and treat hypovolemia, fluids and urinary output

Treat underlying cause, if possible

**Refractory cases:**

1. Demeclocycline
2. Urea
3. Vaptans (caution/controversial treatment, consult an expert)
4. Fludrocortisone
5. Lithium (caution/controversial treatment, consult an expert)
16. HYPERNATREMIA: DIABETES INSIPIDUS

Patients at Risk

Brain: tumors, trauma, infections,
Neoplasm:
  Brain: Craniopharyngiomas, Pituitary Adenoma, Meningioma
  Cancer: lung, breast, Lymphoma, Leukemia
Surgery of Hypothalamus or Supraoptic Region
Induced by: Phenytoin, Ethanol, Lithium
Chronic renal failure
Hypercalcemia
Hypokalemia

Diagnosis

HYPERNATREMIA (Plasma Levels of \( \text{Na}^+ > 145 \text{ mEq/L} \))
POLYURIA (> 30 cc/Kg/24 hours or >2 cc/Kg/h)
POLYDIPSIA
Urinary specific gravity < 1005

Classification of Hyponatremia

<table>
<thead>
<tr>
<th>Plasma levels of ( \text{Na}^+ ) (mEq/L)</th>
<th>Severe: ( \text{Na}^+ &gt; 160 ) (mEq/L)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symptoms</td>
<td>Severe / acute: seizures, coma, death, high fever, intracranial hemorrhage, thrombosis of dural sinuses</td>
</tr>
<tr>
<td>Time</td>
<td>Acute &lt; 48 hours</td>
</tr>
<tr>
<td></td>
<td>Chronic &gt; 48 hours</td>
</tr>
</tbody>
</table>
16. HYPERNATREMIA: DIABETES INSIPIDUS

**Treatment**

Draw blood sample: repeat electrolytes including Ca++, glucose levels, kidney function
Measure urine osmolality, density and Na+, uric acid

**Volume Replacement** with NaCl 0.9% **Normal Saline**

If Hypernatremia is severe and/or acute:
**Dextrose 5% IV bolus** 500 cc and consider hemodialysis

If it is not severe or chronic:

**Aims of Na+ Correction:**
- ↓ 2 mEq/L/h
- ↓ 10 mEq/L over 24 hours until plasma Na+ = 145 mEq/L

**Na+ Correction:**

1. **Calculate the Water Deficit (WD) and correct over 48 hours:**
   
   \[
   \text{Water Deficit} = (\text{TBW} \times \left(\frac{\text{Plasma Na}^+}{140} - 1\right))
   \]
   
   \[
   \text{TBW} = 0.5 \text{ (Female)} \text{ or } 0.6 \text{ (Male)} \times \text{Lean Body Weight}
   \]

2. **Calculate the change in Na:** estimate the effect of 1 liter of infusate on serum Na+
   
   \[
   \text{Change in Na} = \frac{(\text{Infusate Na}^+ - \text{Serum Na}^+)}{\text{TBW} + I}
   \]

3. **Select replacement solution**

<table>
<thead>
<tr>
<th>Solution</th>
<th>Infusate Na+ (mmol/L)</th>
</tr>
</thead>
<tbody>
<tr>
<td>5% Dextrose</td>
<td>0</td>
</tr>
<tr>
<td>0.45% NaCl</td>
<td>77</td>
</tr>
<tr>
<td>0.9% NaCl</td>
<td>154</td>
</tr>
<tr>
<td>Ringer Lactate</td>
<td>130</td>
</tr>
</tbody>
</table>

Repeat plasma levels of Na+ every 4 hours until na+ stabilized, then every 8 hours
Monitor volume status and treat hypovolemia, fluids and urinary output.
Eliminate reversible causes: (stop medications that increase risk)
Treat underlying cause, if possible
Start intake of water as soon as patient is awake

**Other Therapies:**

1. **Vasopressin:** 5 units SUBCUTANEOUS every 6 to 8 hours or
2. **Desmopressin:** 1 mcg SUBCUTANEOUS p.r.n. or
   Intranasal spray 1 BID (10 mcg/spray) or
   Tablets 0.1-0.3 mg p.o. BID
## Classification of Agents

**OSMOTIC AGENTS (>650 mOsm/L)**

Risk of compartment syndrome

- Total parenteral nutrition
- Mannitol
- Calcium chloride - gluconate
- Potassium
- Sodium bicarbonate
- Ampicillin

**VASOCONSTRICTION AGENTS**

Risk of local ischemia

- Norepinephrine (NE)
- Epinephrine (EPI)
- Dopamine (DA)
- Dobutamine (DBA)
- Methylene Blue (MB)
- Vasopressin (V)
- Phenylephrine (PE)

**PH RELATED AGENTS**

Risk of ischemia and coagulation or compartment syndrome

- Phenytoin (purple glove syndrome)
- Sodium Thiopental
- Vancomycin
- Amiodarone
## 17. EXTRAVASATION OF INTRAVENOUS ACCESS

### Treatment

1. **Stop the “iv” infusion**
2. **DO NOT REMOVE THE CATHETER**
3. **ASPIRATE** through the catheter
4. Injection **REVERSAL AGENTS** through the catheter.
5. Remove the catheter
6. Elevate affected limb
7. Apply **WARM** or **COLD** compresses as indicated
8. Surgical consult

### OSMOTIC AGENTS (>650 mOsm/Lt)

**Risk of Compartment Syndrome**

1. **HYALURONIDASE**
   - 15-25 Units.
   - Intradermal and through catheter
2. Topical **Nitroglycerin**
   - 2% Strips over area or Nitroglycerin patch over the area.
3. **COLD COMPRESSES:**
   - For 20 min, 3-4 times a day, 48 to 72 hours.
4. Elevation of extremity

### VASOCONSTRICTION AGENTS

**Risk of local ischemia**

1. **PHENTOLAMINE**
   - (NE,EPI,DA,DBA,PE):
   - 5-10 mg in 20 cc saline, injected multiple times hypodermic needle or through the catheter.
2. Topical Nitroglycerin 2% strips
3. **HEAT** proximal to site, elevation
4. **TERBUTALINE**
   - (NE,EPI,DA,DBA):
   - 1 mg in 10 CC saline inject locally across sites

### PH RELATED AGENTS

**Risk of ischemia and coagulation or compartment syndrome**

1. **DRY HEAT**
2. Elevation of extremity
3. **HYALURONIDASE**

#### AVOID HYALURONIDASE AND ICE PACKS

#### AVOID NEUTRALIZATION OF THE SUBSTANCE

EMERGENCY MANUALS

The purpose of this crisis manual is to be a resource for anesthesiologists and to prepare them for stressful situations that may arise during neurosurgical procedures. It is meant to be a reference only and a cognitive aid in emergency situations. It is NOT a guideline or a protocol that anesthesiologists are obligated to follow. This manual may provide a vehicle for input and practical strategies when facing critical events with neurosurgical patients.
