Abstract

Gap junction (GJ) channels provide direct intercellular communication. A GJ channel consists of two docked hemichannels and each hemichannel is a hexamer of six connexins. Human vascular connexins (Cx37, Cx40, Cx43, and Cx45) can form various types of gap junction channels to synchronize vasodilation/constriction to control local circulation. Most of our knowledge on heterotypic GJs of these vascular connexins comes from studies on rodent connexins. However it is not clear if these human connexins can also form heterotypic GJs. The present study used an *in vitro* expression system to investigate the coupling status and GJ properties of human heterotypic Cx37/Cx40, Cx37/Cx43, and Cx37/Cx45 GJs. Our results showed that Cx37/Cx43 and Cx37/Cx45 GJs, but not Cx37/Cx40 GJs, were functional and with unique rectifying channel properties. The docking between Cx37 and Cx40 could be rescued by designed Cx40 variants. The unique heterotypic Cx37/Cx43 and Cx37/Cx45 GJ properties may help us understand the intercellular communication between vascular cells.

Gap junction, connexin37, V_j -gating, vasculature, myoendothelial junction, patch clamp, endothelium

Co-Authorship Statement

Chapter 2 will be submitted as a manuscript for publication. Electrophysiological data was collected by Nicholas Kiwon Kim. Honghong Chen generated untagged expression vectors for Cx37, Cx40, Cx43, Cx45 and all Cx40 mutant cDNAs.

Acknowledgements

After several months in the Bai lab, I would like to acknowledge fellow colleagues, friends and mentors who helped me in my journey. I would like to thank Benny, Mary Grace, and Mahmoud. In my first year, you all helped me develop my skills in patch clamp technique as well as teach me many life skills to handle graduate studies. Artur, it was a lot of fun having you visit our lab for an entire year. I learned from you that a great deal of effort is always needed to fulfill my passions and goals. Your drive and positive attitude to learn as well as your ability to drink coffee is inspirational and addicting. I thank you for extending my knowledge about patch clamp technique and teaching me about your culture. Do not worry, Brazil is definitely on my travel bucket list. Kelvin and Ushra, you two made my second year quite interesting and it was a pleasure mentoring both of you. You did really well. To the past and present students, although the time I got to know you was brief, I wish you luck in your future endeavors. Hong and Dr. Bai, I would like to express my gratitude for showing a lot of patience and support in developing my research skills. I gained valuable knowledge and still realize that learning or research never ends.

1. Introduction

1.1. Gap Junction Channels

Gap junction (GJ) channels mediate cell-to-cell communication by providing low resistance passages for ions (e.g. K^+), metabolites (e.g. ATP), and small signaling molecules (e.g. cyclic AMP) less than 1 kiloDalton (kDa) in size (Goldberg et al., 1999; Goodenough and Paul, 2009; Kumar and Gilula, 1996). GJ channels are ubiquitously identified throughout tissues and organs of the body, contributing to the maintenance of electrical and metabolic homeostasis of adjacent cells. Their functions become specific to their tissue environment and the individual connexin components. In avascular organs such as the lens of the eyes, GJs maintain homeostasis between cells by mediating the exchange of nutrients and waste product (White et al., 1994). In contrast, GJ channels allow action potential propagation in excitable cells such as cardiomyocytes and electrical synapses of neurons to ensure high conduction velocity of the electrical stimuli throughout the heart and in a neuronal circuit respectively (Barr et al., 1965; Davis et al., 1995).

A GJ channel can be formed as a result of two hemichannels on nearby cells in close proximity with one another (Bai, 2016; Kumar and Gilula, 1996). Each hemichannel (or connexon) is a hexamer of six connexin proteins that dock in a head-to-head manner (Bai, 2016; Saez et al., 2003) (Figure 1-1A). As each cell can express more than one type of connexin isoform, this can lead to the formation of different hemichannels and GJ channels (Sohl, 2004). Homomeric homotypic GJs have both hemichannels comprised of the same connexin subunits. In contrast, the two hemichannels in homomeric heterotypic GJs are different in composition when compared with each other, but contain the same

connexin subunits within each hemichannel. Lastly, heteromeric heterotypic GJs have at least two different types of connexins forming at least one of the two hemichannels (Goodenough and Paul, 2009) (Figure 1-1B). Normally GJ channels cluster with each other to form aggregates known as GJ plaques; however, morphological and freeze-fracture studies have shown individual GJ channels can also be found at the cell-to-cell interface (de Wit et al., 2009; Johnson et al., 1974; Laird, 1996; Sandow and Hill, 2000). Furthermore, mutations in the coding region of connexin genes are associated with several inherited human diseases including congenital hearing loss, lens cataracts, demyelinating X-linked Charcot-Marie-Tooth disease, and oculodentodigital dysplasia (Bergoffen et al., 1993; Laird, 2006; Liu et al., 1997; Shiels et al., 1998).

1.2. Connexin

Connexins are denoted by the species of origin as well as the predicted molecular weight (e.g. mCx37 is the mouse variant of Cx37 and would have a molecular weight of 37 kDA). Nearly all characterized connexin members begin the oligomerization process at the endoplasmic reticulum. They are then trafficked to the plasma membrane through the secretory pathway of the Golgi network (Laird, 1996). However, Cx43 appeared to utilize different intracellular compartments to oligomerize (Laird, 1996; Maza et al., 2003). Upon reaching the plasma membrane, these hemichannels can function as undocked hemichannels, or dock with another hemichannel of a nearby cell to form a GJ channel (Laird, 1996).

Twenty-one connexin genes are identified in the human genome, whereas 20 connexin genes have been found in the mouse genome (Saez et al., 2003; Sohl, 2004). Through detailed analysis in the amino acid sequences of all 21 human connexin genes, a

phylogenetic tree was generated to further classify these connexins into 5 groups (e.g. α , β , γ , δ , ϵ) (Figure 1-1C). These groups became part of their genetic nomenclature (Bai, 2016; Kumar and Gilula, 1996). As extensively discussed in the review (Bai et al., 2018), there are a few differences to note between mouse and human connexins apart from their predicted function to form intercellular channels. First, for some connexins genes, no homologues were identified between the two species such as mCx33 and hCx25. Second, some connexins that share the same name and molecular weight could have up to 29% difference (i.e. Cx46) in their amino acid sequences. Third, mouse and human connexins show similar expression patterns in tissues; however, differences were observed regarding with their docking compatibilities (Bruzzone et al., 1993; Elfgang et al., 1995; Jassim et al., 2016; Ye et al., 2017).

Although there are different isoforms, connexin family members all share similar topological features such as a cytosolic amino terminus and a carboxyl terminus (NT and CT respectively). In addition, there are four alpha helical transmembrane domains (M1-4), two extracellular domains (E1 and E2), and one cytoplasmic loop (CL) (right panel of Figure 1-1A) (Kumar and Gilula, 1996; Milks et al., 1988). With the big contribution from Maeda and fellow colleagues, a crystalized structure of human Cx26 with a resolution of 3.5 Å was resolved in 2009. This helped improve the understanding on GJ structure and highlighted the domains involved in docking (Maeda et al., 2009). In both extracellular domains (E1 and E2), there are three cysteine residues per domain that can form disulfide bridges connecting E1 and E2 within the same connexin (Bai, 2016; Laird, 1996). Interestingly these two domains were found to be highly conserved within the connexin family, especially the three cysteine residues (Bai, 2016; Sohl, 2004). Previous mutation

studies involving the removal of these cysteine residues resulted in non-functional GJ channels; strengthening their crucial role in GJ formation (Dahl et al., 1992; Good et al., 2012). Although the connexins of each hemichannel appear to dock in a one-to-one ratio, a closer inspection revealed that the connexins are staggered in the docking interface (Figure 1-1A,B). In the E1 docking interface, two hydrogen bonds (HBs) were formed with an opposing connexin subunit and another two HBs interacted with another opposing connexin. On the other hand, the E2-E2 docking interface is restricted between two connexins held together by six HBs (Bai et al., 2018). A total of 60 HB are formed when two connexons dock with each other; forming a GJ channel (Bai et al., 2018).

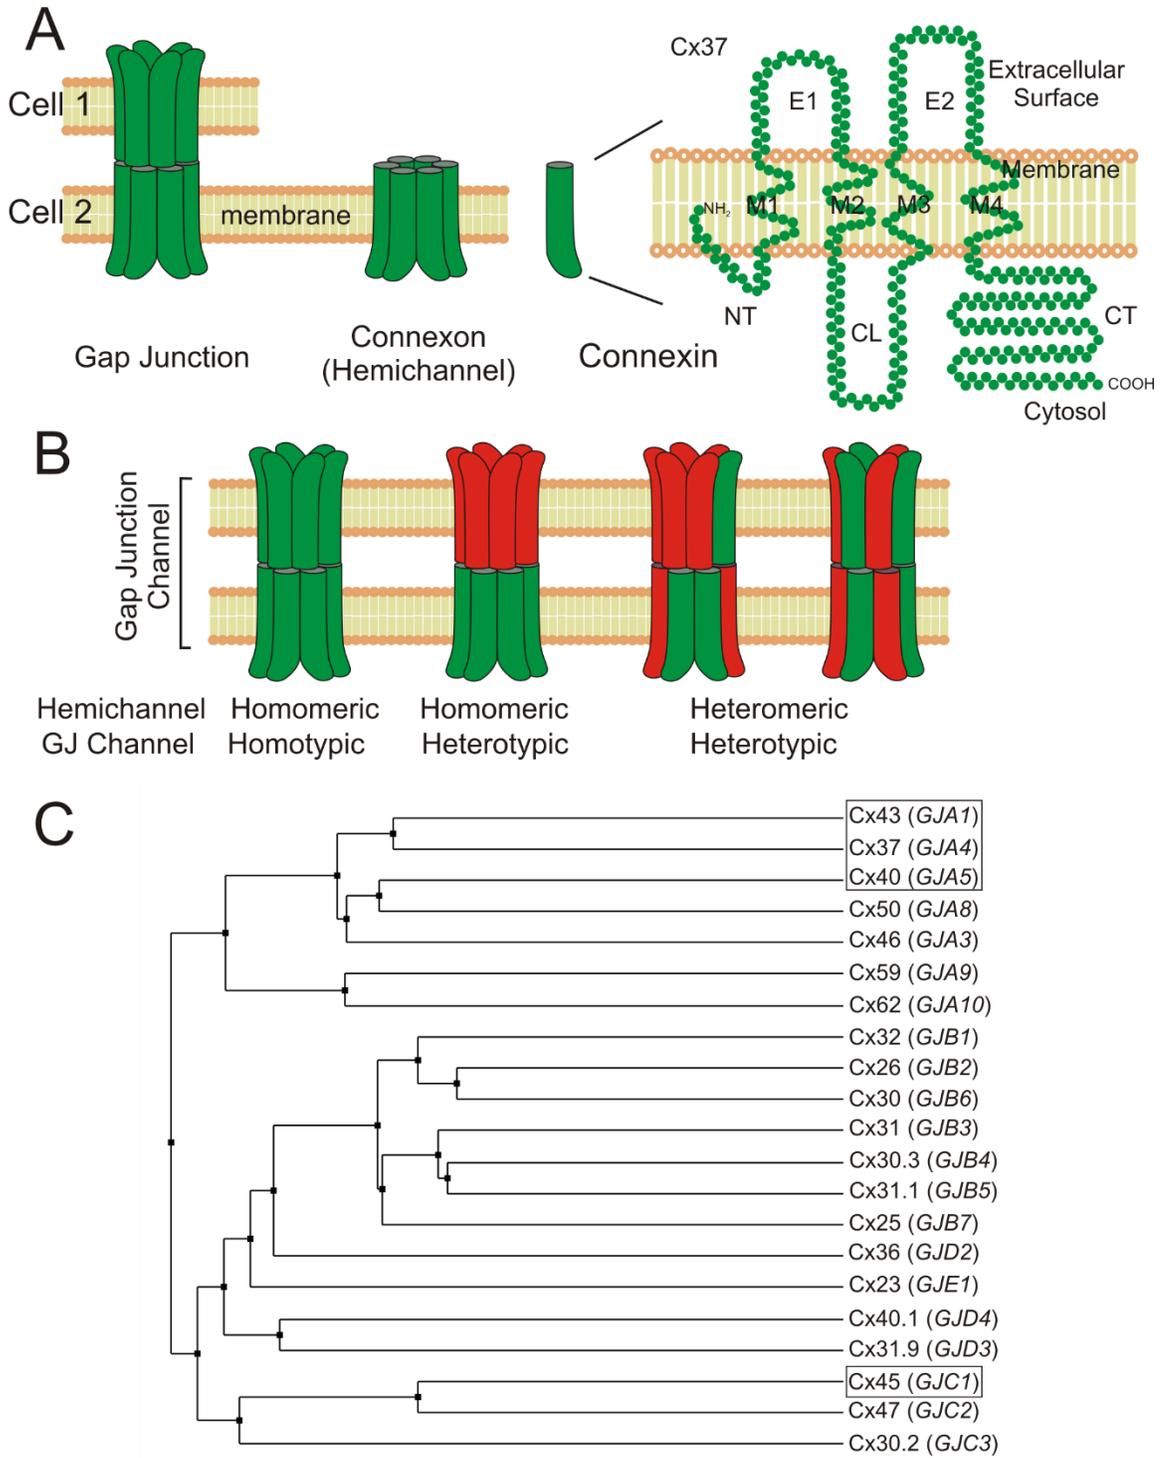

Figure 1-1

Figure 1-1. Gap junction channel composition, structural topology of a single connexin, and dendrogram of 21 human connexins.

(A) GJ channels consist of two connexons (or hemichannels) docked with each other between two neighbouring cells. Each connexon is a hexameric oligomer of connexins. Connexin37 (Cx37), like other connexins, contain four alpha helical transmembrane domains (M1-4), two extracellular loops (E1 and E2), a cytoplasmic loop (CL), a cytosolic amino terminus (NT), and a carboxyl terminus (CT) (Milks et al., 1988). (B) The classification of GJs is dependent on the docked hemichannel composition. (C) Average distance generated using BLOSUM62 from ClustalWS alignment. Connexins pertaining to the vasculature are indicated with square outlines. Different connexins groups are indicated by the alphabetical letters within the gene name (e.g.; A, B, C, D, E correspond to α , β , γ , δ , ϵ respectively). Panels A and B were modified from (Bai et al., 2018).

1.3. Voltage Regulation of GJ channels

Gap junction permeability and conductance can be regulated by many factors including transjunctional voltage and membrane voltage (Gonzalez et al., 2007). Similar to voltage-gated ion channels, GJs exhibit a sensitivity to voltage, which alters the conductance of the channel through a process known as voltage-dependent deactivation or gating (Bukauskas and Verselis, 2004; Gonzalez et al., 2007). Voltage-dependent deactivation can be divided into two types: membrane potential (V_m) and transjunctional potential (V_j). The former refers to the voltage difference between the intracellular and extracellular space of the cell. On the other hand, the latter refers to the voltage difference between the interior of two adjacent cells linked by GJ channels (Gonzalez et al., 2007). The V_m of two cells can vary but the V_j will not be influenced as long as the change in both V_m s are identical (Gonzalez et al., 2007). However when the change in V_m of the two cells are different, a transjunctional voltage gradient is created; resulting in a V_j .

Electrophysiological studies through dual whole-cell patch clamp in *in vitro* expression systems such as *Xenopus oocytes*, HeLa cells, or mouse neuroblastoma (N2A) cells are often used to observe the aforementioned V_j -gating properties of different GJs channels. In preparation for electrophysiological recording, GJ-deficient cell lines such as N2A cells would be transfected with a connexin of interest. Typically, changes in V_j are administered artificially, and the corresponding transjunctional current (I_j) responses are recorded (Jassim et al., 2016; Nouredin et al., 2018; Ye et al., 2017). Activity of multiple GJ channels, reflected by the I_j recordings, is used to create a normalized steady state-to-peak conductance ratio ($G_{j,ss}$) plotted against the respective V_j s. The $G_{j,ss}$ - V_j plot of most GJs can be well fitted with a two-state Boltzmann equation (Spray et al., 1981). This fitting

provides a unique set of Boltzmann parameters which reflect the V_j -gating properties displayed by different GJs.

A common characteristic of GJs is V_j -dependent gating (V_j -gating). Depending on the connexin type, other properties observed include the V_j -gating polarity and kinetics such as the change in the transjunctional conductance (G_j) over time (Bennett and Verselis, 1992). V_j -gating polarity is defined as the voltage polarity at which V_j -gating occurs; closing the hemichannel (Chen-Izu et al., 2001). For example; homotypic Cx45 GJs possess a negative V_j -gating polarity as V_j -gating closes the hemichannel at $-V_{js}$ (Chen-Izu et al., 2001). Furthermore it was suggested that each hemichannel in a GJ contains two V_j -sensitive sensors and two gates connected symmetrically in series, which controls the closure of the GJ channels. As the two gates are connected in series, closing of one gate will affect the voltage distribution of the whole GJ channel which is named the contingent gating theory (Bukauskas and Verselis, 2004; Harris et al., 1981). The theory proposed that the state of one hemichannel is dependent on the state of the other hemichannel; hence acting in a contingent manner (Harris et al., 1981). At the single channel level, multiple conductance states have been observed: a fully open state, one or more subconducting (or residual) states, and a closed state (Bukauskas and Weingart, 1994; Veenstra et al., 1994). Interestingly, single channel GJs appeared to display two distinct V_j -gating mechanisms that are GJ-dependent: fast V_j -gating and slow V_j -gating. These are defined by the transitions between different conducting states over time (Bukauskas and Weingart, 1994). Fast V_j -gating (typical transition time of $<1 - 2$ ms) is the transition between the main open state and subconducting state meanwhile slow V_j -gating (typical transition time of ~ 15 to

60 ms) is the transition between an open or subconducting state to a fully closed state (Bukauskas and Verselis, 2004; Bukauskas and Weingart, 1994).

1.4. Vasculature

Within both human and mouse vasculature, GJ channels have been found between endothelial cells (ECs) and vascular smooth muscle cells (VSMCs) (Figure 1-2) (de Wit et al., 2009). ECs function in syncytium during vasodilation as electrical signal conduction is facilitated by GJ channels (Bagher and Segal, 2011). Similarly VSMCs coupled by GJs are able to synchronize fluctuations in intracellular calcium concentrations which can lead towards spontaneous diameter changes in arteries (Haddock and Hill, 2005). A previous study reported further signal propagation in ECs, as injected current barely attenuated compared to the steep decrease seen in VSMCs (Yamamoto et al., 2001). This suggested that ECs help mediate signal propagation over long distances. The presence of GJs amongst ECs is well established via electron microscopy as they are easily found in large abundance with large GJ plaques (Ko et al., 1999; Yeh et al., 1998). On the other hand, GJs are not as effortlessly detected in VSMCs due to the limited number of GJs and smaller plaque sizes (Beny and Connat, 1992).

1.4.1. Myoendothelial Junction

Although the internal elastic lamina separates ECs and VSMCs, there are fenestrations detected in small arteries (Campbell and Roach, 1981). It is at these sites where ECs and VSMCs can make contact with each other known as myoendothelial junctions, with small vascular beds showing greater numbers of these junctions (Figure 1-2) (de Wit et al., 2009; Sandow and Hill, 2000). The origin of these projections varies between different vessel types, but the majority appears to come from the endothelial side (Sandow

et al., 2003). Within most MEJs, GJ plaques are smaller in size (< 100 nm) with as little as only one GJ channel compared to the larger plaques and several channels found between ECs. (Little et al., 1995; Sandow and Hill, 2000). These observations would explain the difficulty of detecting GJ channels in the MEJs.

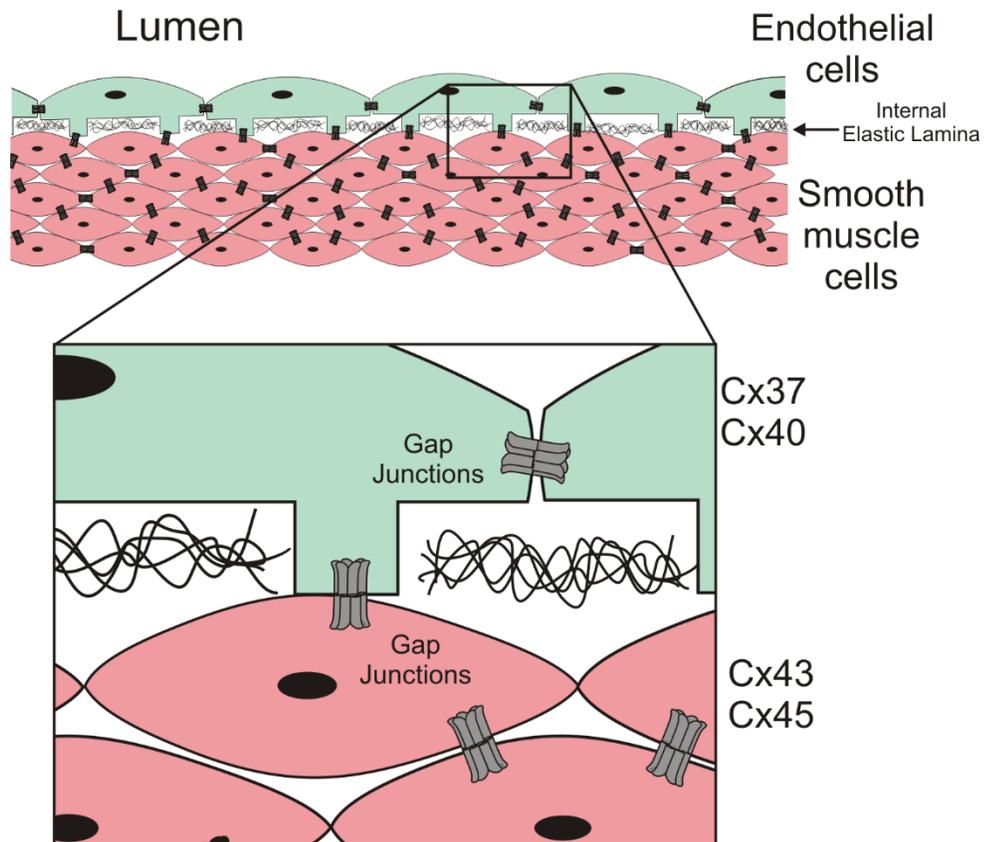

Figure 1-2. Cell type specific expression of Cx37, Cx40, Cx43, and Cx45 in the vasculature.

Abundant expression of Cx37 and Cx40 (Gabriels and Paul, 1998; van Kempen and Jongsma, 1999) are located in the endothelium, whereas Cx43 and Cx45 are abundantly expressed in smooth muscle cells (Bruzzzone et al., 1993; Little et al., 1995; Pogoda et al., 2014; Severs et al., 2001). The expression pattern of these connexins in the vasculature predicted formation of several types of gap junctions (GJs), including homomeric homotypic, homomeric heterotypic, and heteromeric heterotypic GJs

1.4.2. Localization and Knockout Studies of Vascular Connexins

The four connexin isoforms that are often discussed in the vasculature are Cx37, Cx40, Cx43, and Cx45. The first three are α -connexins, but the last belongs in the γ group (Bai, 2016; Willecke et al., 2002). The expressions of these connexins are not uniform, and can vary between species and blood vessel size. Many studies have agreed on the abundant expression of Cx37 and Cx40 in ECs, whereas Cx43 and Cx45 are abundantly expressed in VSMCs (Figure 1-2) (Begandt et al., 2017; Bruzzone et al., 1993; Gabriels and Paul, 1998; Hill et al., 2002; Little et al., 1995; Pogoda et al., 2014; Severs et al., 2001; van Kempen and Jongma, 1999; van Kempen et al., 1995). However it is important to note that these connexins are not confined to the specific cell type, as Cx37 has also been detected in the tunica media of the caudal and basilar arteries (Hill et al., 2002; Rummery et al., 2002). Likewise Cx40 and Cx43 may be expressed in both cell types (Gabriels and Paul, 1998; Little et al., 1995; van Kempen and Jongma, 1999).

Knock-out (KO) studies in mice have shown that the removal of connexin genes can result in severe malformations in the vasculature (Sohl, 2004). Cx45 KO mice exhibited impaired vascular development and organization of blood vessels, which eventually led to death early in the embryonic stage (E9.5 to E10.5) (Kruger et al., 2000). For Cx43 KO mice, several genes associated with differentiation and function of vascular cells were modified and altered the cell signaling pathways regulating vasculogenesis and angiogenesis (Clauss et al., 2006; Walker et al., 2005). Moreover, embryos died at birth due to blockage of the right ventricular outflow tract (Reaume et al., 1995). On the other hand, mice were viable from the individual Cx40 or Cx37 KOs (Figuroa and Duling, 2009; Kirchhoff et al., 1998; Simon et al., 1997). Cx40 deficient mice embryos displayed small

defects along the cardiac septum and predisposition towards arrhythmias (Figuroa and Duling, 2009; Kirchhoff et al., 1998). Interestingly, no vascular abnormalities including heart dysfunction were observed with Cx37 deficient mice except that females were reported to be infertile (Simon et al., 1997). However with Cx37 and Cx40 double KO, mice pups died around birth due to severe vascular abnormalities with pronounced dilatations (Simon and McWhorter, 2003). These studies highlight an important role of these connexins in vasculature development and function.

1.5. Rationale and Hypothesis

There are four connexin isoforms expressed in the vasculature: Cx37, Cx40, Cx43, and Cx45. It was noted that they belong in the same group of docking-compatible connexins (Bai et al., 2018; Elfgang et al., 1995). A previous study done by Elfgang and colleagues revealed that mCx37 is able to form homomeric heterotypic GJ channels with other mouse connexins including mCx40, mCx43, and mCx45. This was demonstrated through the transfer of Lucifer yellow dye in transfected HeLa cells (Elfgang et al., 1995). However, the heterotypic GJ channel properties of hCx37 have not been investigated. The importance of the present study is to determine if the heterotypic GJ channel formation of hCx37 is different as previous studies on the other three human vascular connexins demonstrated different heterotypic docking behaviours compared to mouse counterparts (Jassim et al., 2016; Ye et al., 2017). The difference in the amino acid sequence identity between mouse and human vascular connexins can be as high as 17% (Sohl, 2004). This difference in amino acid sequence identity may potentially induce selectivity in the heterotypic interaction and limit different GJ formation (Bruzzone et al., 1993; Jassim et

al., 2016; Ye et al., 2017). It is hypothesized that human Cx37 is able to form homomeric heterotypic GJs with other human vascular connexins, including Cx40, Cx43, or Cx45.

1.6. Objectives

- i. To determine if hCx37 is able to form functional homomeric heterotypic GJs with human Cx40, Cx43, or Cx45 in N2A cells, each of these connexins were transfected with an untagged fluorescent protein (e.g. Cx37-IRES-GFP, Cx40-IRES-DsRed, Cx43-IRES-DsRed, or Cx45-IRES-DsRed). Using dual whole-cell patch clamp, transjunctional voltages (V_{js}) will be administered to cell pairs with positive expression of GFP (or Ds-Red). Next, a transjunctional current (I_j) will be measured at each respective V_{js} . The coupling percentage and coupling conductance (G_j) will be analyzed on homotypic and heterotypic cell pairs.
- ii. To explore the V_j -gating properties for each homotypic or heterotypic GJ channels. The normalized steady state conductance ($G_{j,ss}$) will be plotted as a function of the respective V_{js} and fitted with a Boltzmann equation for each V_j polarity. From this, the extent of the conductance change will be observed via the Boltzmann parameters.

2. Human Cx37 does not form heterotypic gap junction channels with Cx40

2.1. Abstract

Human vascular connexins (Cx37, Cx40, Cx43, and Cx45) can form various types of gap junction channels to synchronize vasodilation/constriction to control local circulation. Most of our knowledge on heterotypic gap junctions of these vascular connexins was from studies on rodent connexins. In human vasculature, the same connexins exist, but whether these human connexins can form heterotypic GJs as those of rodents have not been fully studied. Here we used in vitro expression system to study the coupling status and GJ properties of human heterotypic Cx37/Cx40, Cx37/Cx43, and Cx37/Cx45 GJs. Our results showed that Cx37/Cx43 and Cx37/Cx45 GJs, but not Cx37/Cx40 GJs, were functional and each with unique rectifying channel properties. The failure of docking between Cx37 and Cx40 could be rescued by designed Cx40 variants. The heterotypic Cx37/Cx43 and Cx37/Cx45 GJ properties may help us in understanding the intercellular communication between vascular cells.

2.2. Introduction

Gap junction (GJ) channels provide direct passages for ions, metabolites, and small signalling molecules less than 1 kiloDalton (kDA) in size between two adjacent cells (Goldberg et al., 1999; Goodenough and Paul, 2009; Kumar and Gilula, 1996). GJ channels are formed from two properly docked hemichannels (or connexons), each of which is a hexamer of connexins (Bai, 2016; Saez et al., 2003). There are 21 connexin genes in the human genome (20 connexin genes in the mouse genome) encoding different connexins

commonly showing tissue-specific expression pattern (Saez et al., 2003; Sohl, 2004). All connexins are predicted to have a similar topological structure with four transmembrane domains (M1-4), two extracellular loops (E1 and E2), a cytoplasmic loop (CL), and with both amino and carboxyl terminus (NT and CT, respectively) in the cytosol (Kumar and Gilula, 1996; Milks et al., 1988). Most connexins have been shown to be able to form functional GJs to mediate gap junctional intercellular communications between cells from the same tissue (most commonly in the form of homotypic GJs) as well as between cells from different tissues (commonly via heterotypic GJs if these cells express different set of connexins). The functional consequence of GJs is to synchronize physiological activities in a variety of tissues and organs (Bennett and Verselis, 1992; Bruzzone et al., 1993; Goodenough and Paul, 2009; Kumar and Gilula, 1996).

Within the vasculature, GJ channels are found at the cell junctions between endothelial cells (ECs), in the junctions between vascular smooth muscle cells (VSMCs), and also at the myoendothelial junctions between these two cells (de Wit et al., 2009). In large arteries, an internal elastic lamina is found to fully separate ECs from VSMCs, but in small arteries and arterioles the internal elastic lamina shows fenestrations, where endothelial cells often project out to make direct contact with VSMCs forming myoendothelial gap junctions (MEGJs) (Campbell and Roach, 1981; de Wit et al., 2009; Sandow and Hill, 2000). Four connexins, Cx37, Cx40, Cx43, and Cx45, have been identified in the vasculature with Cx37 and Cx40 preferentially expressed in the ECs (Gabriels and Paul, 1998; van Kempen and Jongasma, 1999) and Cx43 and Cx45 were found in the VSMCs (Bruzzone et al., 1993; Little et al., 1995; Pogoda et al., 2014; Severs et al., 2001). Lower level of expression of Cx43 in ECs and Cx37 in VSMCs were also reported

(Gabriels and Paul, 1998; Little et al., 1995; Rummery et al., 2002; Severs et al., 2001; van Kempen and Jongma, 1999). Cell type specific expression of different connexins in the small arteries predicted formation of homomeric homotypic, homomeric heterotypic, and heteromeric heterotypic GJs in ECs, VSMCs, and at the junctions between these cells. Previous studies on heterotypic docking compatibility of these vascular connexins were almost exclusively on rodent connexins. Limited information is available on the functional status of heterotypic GJs and their channel properties of human vascular connexins, especially on the heterotypic docking compatibility of human Cx37 with other vascular connexins (Cx40, Cx43, and Cx45), leaving an important knowledge gap for our understanding of human vascular GJs.

Knowledge accumulated from studies on rodent connexins revealed that Cx37, Cx40, Cx43, and Cx45 belong to the same group of docking-compatible connexins and each of them was almost fully capable of forming heterotypic GJs with each other (Bai, 2016; Brink et al., 1997; Elenes et al., 2001; Elfgang et al., 1995; Hennemann et al., 1992; Rackauskas et al., 2007). For example, mouse Cx37 was reported to be able to form homomeric heterotypic GJs channels with mouse Cx40, Cx43, or Cx45, to allow successful intercellular transfer of Lucifer Yellow in transfected HeLa cells (Elfgang et al., 1995). Correspondingly electrical coupling in transfected N2A cells or oocyte expression system indicated that Cx37 can form heterotypic GJ channels with Cx40 or Cx43 respectively (Brink et al., 1997; Hennemann et al., 1992). However studies on human vascular connexins revealed that Cx40 showed virtually no coupling when docked with Cx43 or Cx45, distinct from those observed in rodent connexins (Jassim et al., 2016; Ye et al., 2017).

The ability of Cx37 to dock with other vascular connexins (Cx40, Cx43 and Cx45) has not been studied.

It is hypothesized that human Cx37 is able to form homomeric heterotypic GJs with Cx40, Cx43, or Cx45 which may play a role in GJ coupling between ECs, VSMCs or EC-VSMCs. Our *in vitro* study showed that cells expressing human Cx37 was able to form functional heterotypic GJs with cells expressing Cx43 or Cx45, but not with cells expressing Cx40. Designed docking variants in Cx40 E1 or E2 domains successfully established heterotypic docking with Cx37. Both Cx37/Cx43 and Cx37/Cx45 GJs showed unique V_j -gating properties, which could be modulated by a few millivolts difference in all pairs' resting membrane potentials. Characterizing the properties of these heterotypic GJs can reveal how vascular GJs are being dynamically regulated by transjunctional voltage.

2.3. Materials and Methods

2.3.1. Plasmid construction

Human Cx37 was generously provided by Dr. Dale Laird (University of Western Ontario) and was cloned into pIRES2-EGFP vector to have Cx37-IRES-GFP with following primers:

Forward: 5' GGCACTCGAGATGGGTGACTGGGGC3'

Reverse: 5' ACCGGATCCTTATACATACTGCTTCTTAGAAGC 3'

Human Cx40-IRES-DsRed and Cx45-IRES-DsRed were generated as previously described (Jassim et al., 2016; Ye et al., 2017). Cx40-IRES-DsRed were used as templates to generate untagged individual point mutants (D55N and P193Q) similar to those described earlier (Jassim et al., 2016). Cx43-IRES-DsRed was generated from Cx43-IRES-GFP into a pIRES2-DsRed2 vector between restriction sites EcoR1 and BglII.

2.3.2. Cell culture and transient transfections

Gap junction (GJ) deficient mouse neuroblastoma (N2A) cells (American Type Culture Collection, Manassas, VA, USA) were grown in Dulbecco's Modified Eagle's Medium (DMEM) (Life Technologies Corporation, Grand Island, NY, USA) containing 4.5 g/L D-(+)-glucose, 584 mg/L L-glutamine, 110 mg/L sodium pyruvate, 10% fetal bovine serum (FBS), 1% penicillin, and 1% streptomycin, in an incubator with 5% CO₂ at 37°C (Sun et al., 2013). N2A cells were transfected with 1.0 µg of a cDNA construct and 2 µL of X-tremeGENE HP DNA transfection reagent (Roche Diagnostics GmbH, Indianapolis, IN, USA) in Opti-MEM + GlutaMAX-I medium for 5 hours. At the end of transfection, the medium was changed back to FBS-containing DMEM and incubated overnight. Next day transfected N2A cells were replated on glass coverslips for an hour

prior to transfer to recording chamber. Cell pairs with both cells expressing of Cx37-IRES-GFP (or Cx40, Cx43, Cx45, each of them in IRES-DsRed vector) were selected for homotypic GJ studies (Supplemental Figure 2-1). For heterotypic GJ studies, Cx37-IRES-GFP transfected cells were mixed with cells transfected with Cx40-IRES-DsRed, Cx43-IRES-DsRed, or Cx45-IRES-DsRed and replated on glass coverslips to allow formation of heterotypic cell pairs with one expressing GFP and the other expressing DsRed.

2.3.3. Electrophysiological recording

Glass coverslips containing transfected cells were transferred to a recording chamber on an inverted microscope (Leica DM IRB, Ontario, Canada) containing extracellular solution (ECS) at room temperature (22-24°C). The ECS contained (in mM): 135 NaCl, 2 CsCl, 2 CaCl₂, 1MgCl₂, 1 BaCl₂, 10 HEPES, 5 KCl, 5 D-(+)-glucose, 2 Sodium pyruvate, pH 7.4 with 1M NaOH, and osmolarity of 310-320 mOsm. Whole cell voltage clamp was performed on each of the cell pair with Axopatch 200B amplifier (Molecular Devices, Sunnyvale, CA, USA). Patch pipette was pulled with a puller (PC-10, Narishige International USA Inc., Amityville, NY, USA) and was filled with intracellular solution (ICS) containing (in mM): 130 CsCl, 10 EGTA, 0.5 CaCl₂, 5 Na₂ATP, 10 HEPES, pH 7.2 with 1 M CsOH, and osmolarity of 290-300 mOsm. Each of the cell pair was voltage clamped at 0 mV. In one cell, a series of voltage pulses was applied for 7 seconds. The other cell of the pair was constantly held at 0 mV to record gap junctional current (I_j). Currents were low-pass filtered (Bessel filter at 1 kHz) and recorded using pClamp9.2 in a computer at a sampling rate of 10 kHz via an AD/DA converter (Digidata 1322A, Molecular Devices, Sunnyvale, CA, USA).

2.3.4. Transjunctional voltage dependent gating

Transjunctional voltage (V_j) dependent gating (V_j -gating) was studied in homotypic and heterotypic cell pairs. Voltage pulses of ± 5 , ± 20 to ± 100 mV with 20 mV increments were delivered in one of the cell pair to establish V_{js} and transjunctional currents (I_{js}) were recorded in the other cell. In most cases, I_{js} peaked at the beginning and then deactivated (especially with high V_{js} , ± 40 to ± 100 mV) to a steady-state near the end of a 7 second V_j pulse. Gap junctional conductance (G_j) was calculated ($G_j = I_j/V_j$). The steady state G_j was normalized to the peak G_j to obtain a normalized steady-state junctional conductance ($G_{j,ss}$) for each tested V_{js} . The $G_{j,ss}$ were then plotted with V_{js} to obtain a $G_{j,ss}$ - V_j plot, which could normally fit well with a two-state Boltzmann equation for each V_j polarity (Jassim et al., 2016). Boltzmann parameters, V_0 , G_{min} , G_{max} , A , were determined for each GJ. V_0 is the voltage when the conductance is reduced by half $[(G_{max} - G_{min})/2]$, G_{min} is the normalized voltage-insensitive residual conductance, while G_{max} represents the maximum normalized conductance, and A is the slope of the curve which reflects V_j -gating sensitivity (Spray et al., 1981).

$$G_{j,ss} = \left(\frac{(G_{max} - G_{min})}{1 + e^{A(V_j - V_0)}} \right) + G_{min}$$

2.3.5. Statistical Analysis

Data are expressed as mean \pm SEM. Kruskal Wallis followed by a Dunn's post-hoc test were used to compare multiple groups of non-parametric data, as specified. One-way ANOVA was used to compare multiple groups of data with Gaussian distribution. One sample t -test was used to test if the normalized $G_{j,ss}$ was different from the theoretical value of 1 for the long V_j pulse (15 seconds) experiment. Statistical significance is indicated with

the asterisks on the graphs only for biologically meaningful group comparisons ($*P < 0.05$; $**P < 0.01$; or $***P < 0.001$).

2.4. Results

2.4.1 Human Cx37, Cx40, Cx43, and Cx45 formed functional homotypic gap junction channels

N2A cells were transfected with expression vectors containing one of the vascular connexins and each with an untagged fluorescent protein (e.g. Cx37-IRES-GFP, Cx40-IRES-DsRed, Cx43-IRES-DsRed, or Cx45-IRES-DsRed). Cell pairs with positive expression of GFP (or DsRed) were voltage clamped using dual whole cell patch clamp technique. Majority of cell pairs expressing Cx37 showed transjunctional currents (I_j s) in response to a V_j pulse (+20 mV, Figure 2-1A), indicating successful formation of Cx37 GJs. Coupling percentage for cell pairs expressing Cx37 was calculated for each transfection and the average coupling% of ten transfections was plotted as a bar graph (Figure 2-1B). The average coupling conductance (G_j) of Cx37 expressing cell pairs was obtained and plotted (Figure 2-1C). Cell pairs expressing Cx40, Cx43, or Cx45 showed similar coupling% and G_j as those of Cx37, except the average of Cx45 G_j was significantly lower than that of Cx37 (Figure 2-1C, $p < 0.01$). I_j s of Cx37, Cx40, or Cx43 were typically stable during a 20 mV V_j pulse, except I_j of Cx45, where a time-dependent deactivation was routinely observed (Figure 2-1A). The averaged Cx45 G_j is the lowest and that of Cx43 is the highest in the tested GJs.

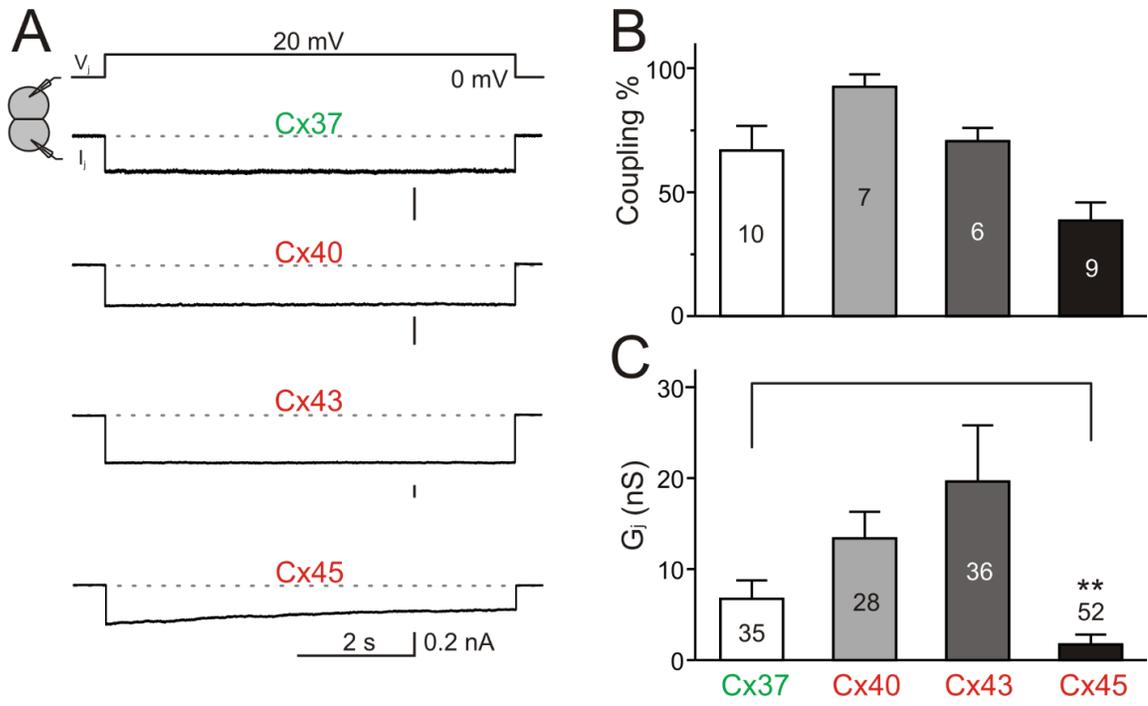

Figure 2-1

Figure 2-1. Coupling percentage and conductance of human homotypic vascular gap junction (GJ) channels

(A) Dual whole cell patch clamp technique was used to measure transjunctional current (I_j) from N2A cell pairs expressing Cx37, Cx40, Cx43, or Cx45 in response to a +20 mV V_j pulse. The green Cx37 and red Cx40, Cx43, or Cx45 text indicate untagged reporters (GFP or DsRed) were expressed with these connexins. (B) Bar graph summarizes the average coupling percentage (coupling%) of cell pairs expressing homotypic Cx37, Cx40, Cx43, or Cx45 for each transfection. Cx37 cell pairs showed similar coupling% as that of each tested connexin. The total number of independent transfusions is indicated within each bar. (C) Bar graph illustrates the average transjunctional conductance (G_j) of all cell pairs expressing the connexins. The G_j was calculated from initial I_j s of cell pairs showing time-dependent changes. A Kruskal-Wallis test followed by Dunn's multiple comparison test showed the G_j of Cx37 was similar to those of Cx40 and Cx43, but significantly greater than Cx45 G_j ($p < 0.05$). The total number of recorded cell pairs is indicated on each bar.

2.4.2 Cx37 formed functional heterotypic GJs with Cx43 or Cx45 but not with Cx40

To test if human Cx37 can form functional heterotypic GJs with other vascular connexins, cells expressing Cx37 (with untagged GFP) were mixed with cells expressing Cx40, Cx43, or Cx45 (all with untagged DsRed). Heterotypic cell pairs (one GFP+ and the other DsRed+) were selected to test their coupling status (coupling%) and coupling conductance (G_j). Most of heterotypic Cx37/Cx43 or Cx37/Cx45 cell pairs formed functional GJs similar to the levels of their respective homotypic GJs (Figure 2-2B). Only $19 \pm 10\%$ of heterotypic Cx37/Cx40 cell pairs was able to form functional GJs, which was significantly lower than that of Cx40 GJ ($p < 0.01$, Figure 2-2B), but not statistically different from that of Cx37. The G_j of the heterotypic GJs was measured and plotted with their respective homotypic GJs (Figure 2-2C). Heterotypic Cx37/Cx43 and Cx37/Cx45 GJs showed similar level of G_j as those of their respective homotypic GJs. However, Cx37/Cx40 GJs displayed a significantly lower G_j than homotypic Cx37 or Cx40 GJs (Figure 2-2C, $p < 0.01$). Combined lower coupling% and G_j of Cx37/Cx40 GJs indicate that Cx37 is unlikely to form heterotypic GJs with Cx40.

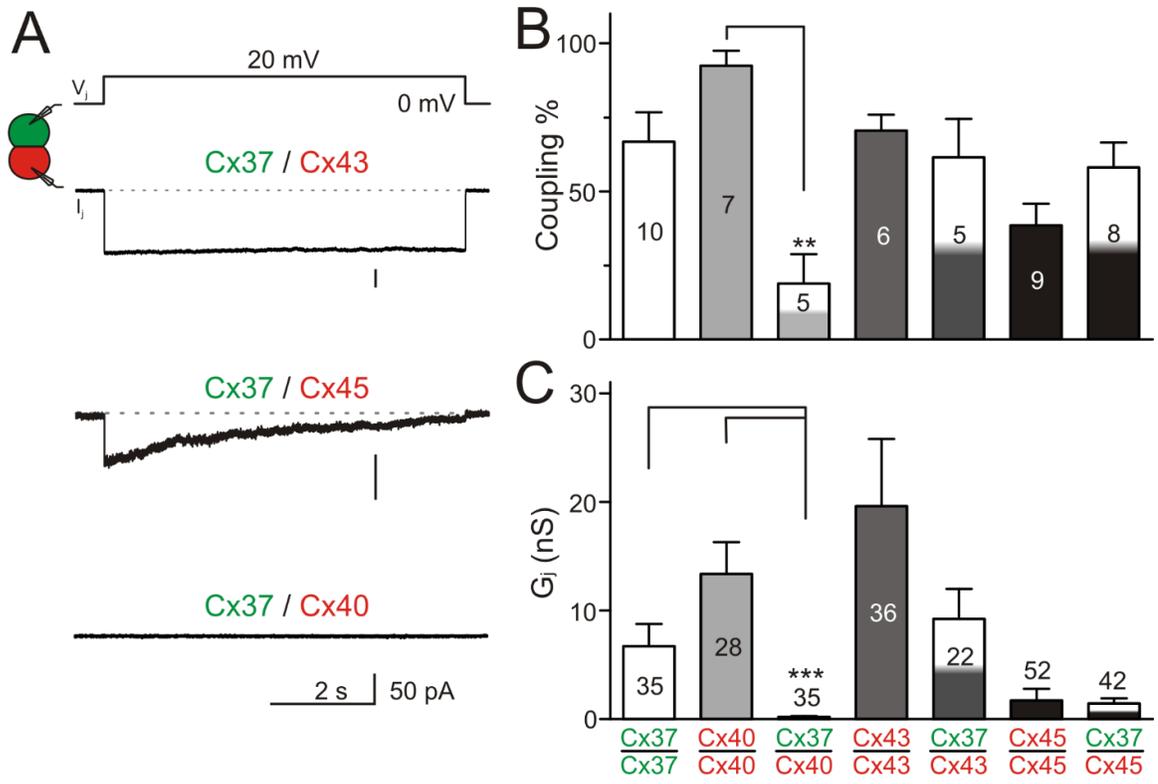

Figure 2-2

Figure 2-2. Coupling percentage and G_j of human heterotypic Cx37/Cx40, Cx37/Cx43, and Cx37/Cx45 gap junctions.

(A) V_j (20 mV)-induced I_j s recorded from N2A cell pairs expressing Cx37 in one and Cx43, Cx45, or Cx40, in the other. Functional heterotypic Cx37/Cx43, or Cx37/Cx45 GJs could be formed, but most of the Cx37/Cx40 cell pairs failed to show I_j . (B) Bar graph summarizes the coupling% of heterotypic Cx37/Cx40, Cx37/Cx43, or Cx37/Cx45 GJs. A significantly lower coupling% was observed for Cx37/Cx40 cell pairs than that of homotypic Cx40 ($p < 0.01$), but not with homotypic Cx37. The total number of independent transfection is indicated on each bar. (C) Bar graph illustrates the coupling conductance (G_j) of heterotypic cell pairs as indicated. Cx37/Cx40 showed a significantly decreased G_j compared to each of the homotypic GJs ($p < 0.001$). The total number of recorded cell pairs is indicated on each bar. Data for homotypic Cx37 and Cx40 GJs were identical as those presented in Figure 2-1 for easy comparison.

2.4.3 V_j -gating properties of homotypic vascular GJs

To investigate the transjunctional voltage dependent I_j deactivation (V_j -gating) of cell pairs forming homotypic Cx37, Cx40, Cx43 or Cx45 GJs, the I_j s were measured in response to a series of V_j pulses (as shown in Figure 2-3A). The I_j s of cell pairs expressing these connexins showed symmetrical V_j -dependent deactivation with different V_j -gating properties. For Cx37 GJs, when V_j absolute value was ≤ 20 mV, I_j s showed no deactivation. I_j s, in response to V_j s in the range of ± 40 to ± 100 mV, showed strong deactivation. The normalized steady state conductance ($G_{j,ss}$) was plotted as a function of V_j (open grey circles in Figure 2-3B), which could be well fitted by a Boltzmann equation for each V_j polarity (smooth dashed grey lines in Figure 2-3B). V_j -gating of Cx40 (black filled circles in the middle panel of Figure 2-3B) or Cx45 (black filled circles in the bottom panel of Figure 2-3B) GJs were also studied using identical V_j protocol. As shown in Figure 2-3B, $G_{j,ss}$ - V_j plots could be well fitted with Boltzmann equations for both Cx40 and Cx45 GJs. Comparing with the Boltzmann fitting parameters of Cx37 GJs, the Cx40 GJ showed a larger V_0 , with similar G_{min} and A , while Cx45 GJs showed lower G_{min} , and V_0 but similar A (Table 2-1). The Cx37 GJ Boltzmann fitting curves (smooth dashed grey lines) were plotted onto the $G_{j,ss}$ - V_j plots of Cx40 and Cx45 GJs for easy comparison (Figure 2-3B). Under the same experimental conditions, the V_j -gating analysis of Cx43 expressing cell pairs was not possible due to G_j level was too high to maintain proper voltage clamp.

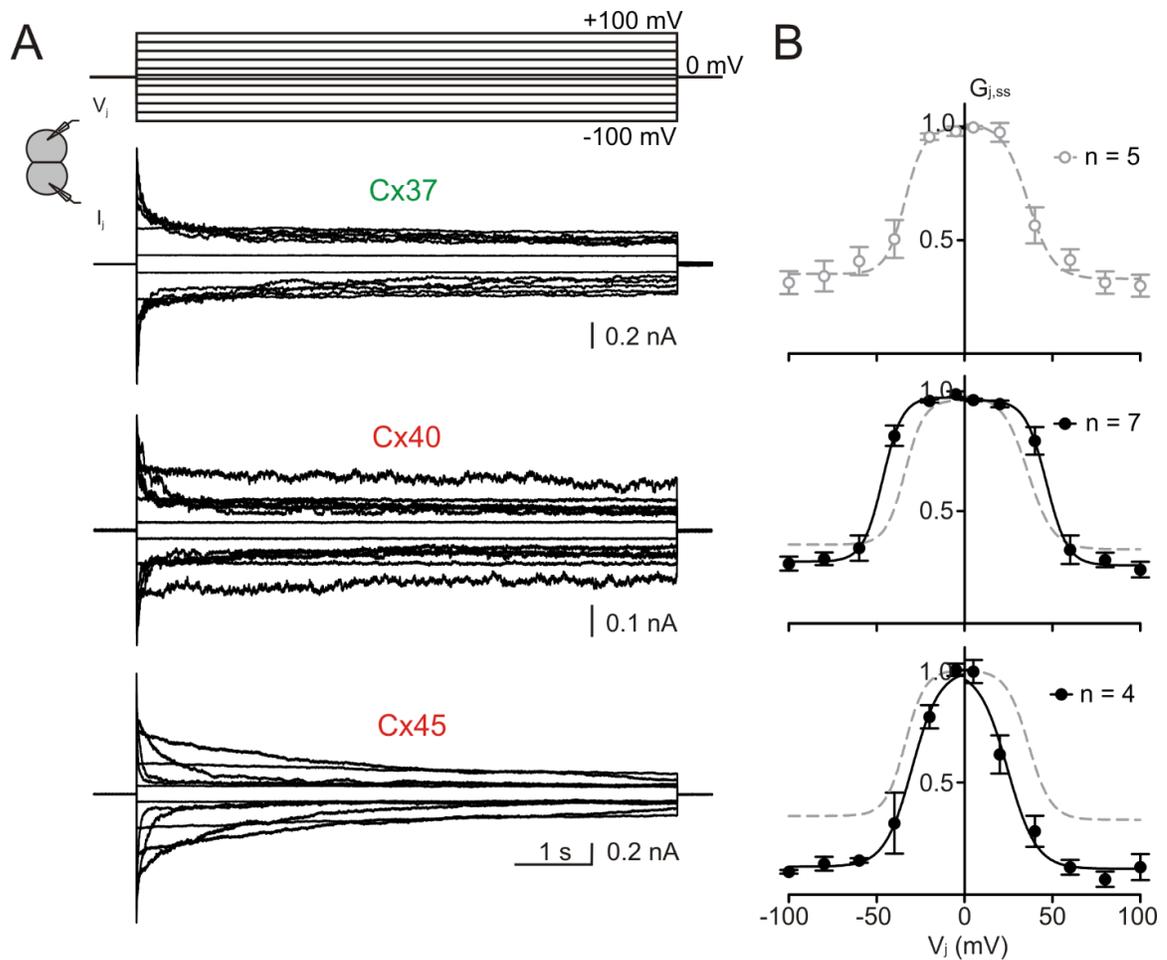

Figure 2-3. V_j -gating of homotypic Cx37, Cx40, and Cx45 GJs.

(A) Superimposed junctional currents (I_j s) were recorded from cell pairs expressing homotypic Cx37, Cx40, or Cx45 GJs in response to a series of V_j pulses (± 5 , ± 20 to ± 100 mV with 20 mV increment). (B) Normalized steady state junctional conductance, $G_{j,ss}$, (a ratio of steady state G_j to the initial G_j) of Cx37 (open grey circles), Cx40, and Cx45 (middle and bottom panels respectively, black filled circles) were plotted as a function of V_j s. Boltzmann equations were used to fit $G_{j,ss} - V_j$ plots for each of these homotypic GJs. The Boltzmann fitting of Cx37 GJ (dashed grey lines were superimposed on every plot for comparison). Number of cell pairs for each plot is indicated.

2.4.4 V_j -gating properties of heterotypic Cx37/Cx43 and Cx37/Cx45 GJs

The same twelve voltage pulses were delivered to one of the heterotypic Cx37/Cx43 or Cx37/Cx45 cell pairs, the typical induced junctional currents (I_j s) showed strong V_j -gating when Cx37 cell with $+V_{js}$ (or when Cx43 or Cx45 with $-V_{js}$), but at the opposite V_{js} (i.e. Cx37 with $-V_{js}$ or Cx43, or Cx45 with $+V_{js}$), little V_j -gating was observed for Cx37/Cx43 GJ or even reverse V_j -gating for Cx37/Cx45 GJ (Figure 2-4A). The V_j levels sufficient to induce V_j -gating appeared to be different for these two heterotypic GJs with Cx37/Cx43 GJ in the range of +40 to +100 mV (on Cx37 or -40 to -100 mV on Cx43) and Cx37/Cx45 GJ in the range of +20 to +100 mV (on Cx37 or -20 to -100 mV on Cx45). $G_{j,ss} - V_j$ plots were generated for Cx37/Cx43 and Cx37/Cx45 GJs and in both cases the data were fitted well with Boltzmann equations when Cx37 with $+V_j$ (or when Cx43 or Cx45 with $-V_j$) (Figure 2-4B), but not the opposite V_j . The Boltzmann fitting parameters are listed in Table 2-1. The V_0 of Cx37/Cx43 GJ was significantly higher than that of Cx37 GJ and the G_{min} and V_0 of Cx37/Cx45 GJ were significantly lower than those of Cx37 GJ, but none of the Boltzmann fitting parameters were different from those of Cx45 GJ (Table 2-1).

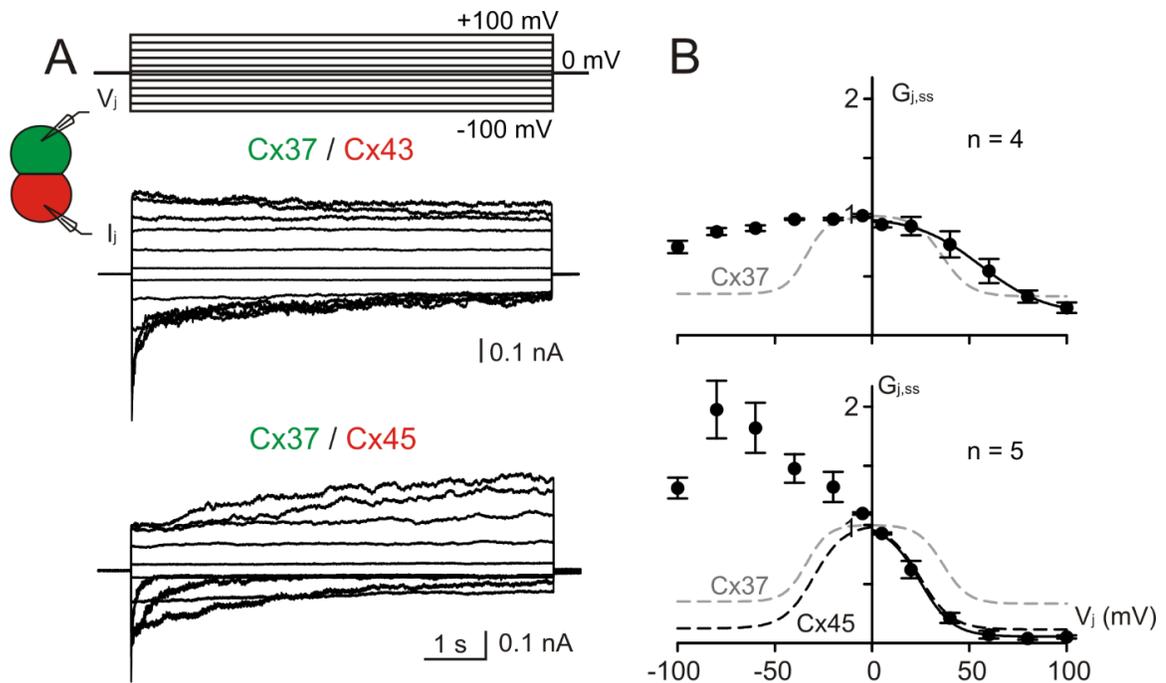

Figure 2-4. V_j -gating of heterotypic Cx37/Cx43 and Cx37/Cx45 GJs.

(A) Superimposed I_j s from heterotypic Cx37/Cx43 or Cx37/Cx45 cell pairs in response to a series of V_j pulses as indicated. (B) Normalized steady state junctional conductance, $G_{j,ss}$, of Cx37/Cx43 or Cx37/Cx45 were plotted with tested V_j s. The data of $G_{j,ss} - V_j$ plot when Cx37 cell with $+V_j$ (or when Cx43 or Cx45 with $-V_j$) could be well fitted with a Boltzmann equation for each of Cx37/Cx43 or Cx37/Cx45 GJs. Boltzmann fitting curves of V_j -gating of homotypic Cx37 (smooth grey dashed lines) or Cx45 (smooth black dashed lines) GJ were superimposed on the plots for easy comparison (smooth black lines).

The I_j s of these two heterotypic GJs displayed some interesting features. For example, the amplitude of the initial inward (defined by the Cx43 or Cx45 cell) junctional currents, $I_{j,ini}$, induced by a V_j appeared to be larger than the corresponding outward $I_{j,ini}$ for both heterotypic GJs (Figure 2-5B). However, the amplitude of the end of inward junctional currents, $I_{j,end}$, were much lower than the corresponding outward $I_{j,end}$ (Figure 2-5B). To quantitatively describe this, we calculated the ratio of junctional conductance $G_j(-)/G_j(+)$ for both the $I_{j,ini}$ and $I_{j,end}$ and plotted with the absolute V_j s (Figure 2-5C). It is very interesting to observe that the ratio $G_j(-)/G_j(+)$ for Cx37/Cx43 GJs were V_j dependent ($P < 0.01$ for the initial [open triangles] and $P = 0.01$ for the end [grey triangles]). But the ratio $G_j(-)/G_j(+)$ for Cx37/Cx45 GJs failed to show any V_j dependence for both the initial and end of the I_j s ($P > 0.05$ for both cases).

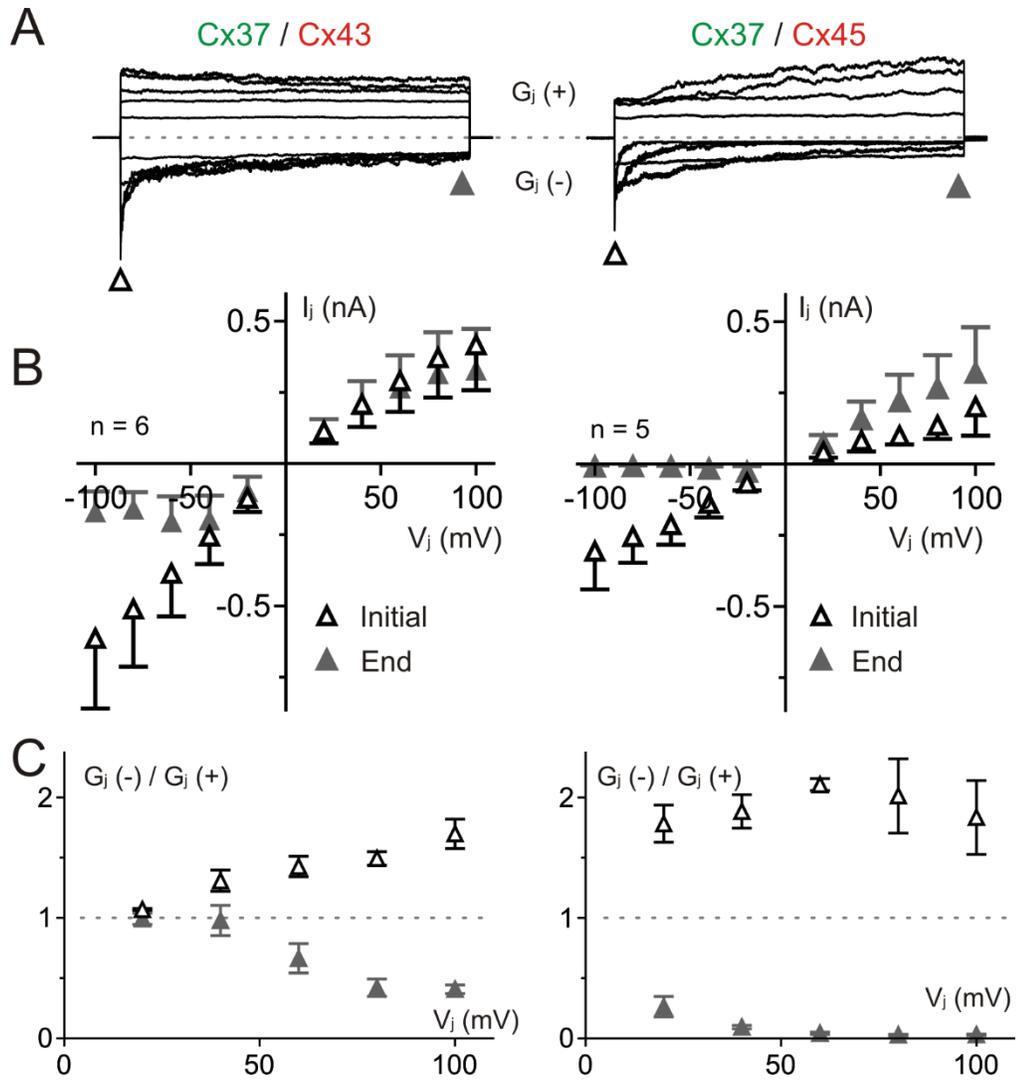

Figure 2-5

Figure 2-5. Heterotypic Cx37/Cx43 and Cx37/Cx45 GJs showed similar and different rectifying properties.

(A) Same I_j s as shown in Figure 2-4A are shown here to illustrate measurement at the initial (open triangle) and the end (grey filled triangle) of each I_j and the definition of conductance $G_j(+)$ when Cx43 or Cx45 with $+V_j$ s and the conductance $G_j(-)$ when Cx43 or Cx45 with $-V_j$ s. (B) $I_j - V_j$ plots were constructed for Cx37/Cx43 and Cx37/Cx45 GJs for both the initial (black open triangles) and end (filled grey triangles) of the I_j response. (C) The ratios of $G_j(-)/G_j(+)$ for the initial (black open triangles) and end (filled grey triangles) were plotted with V_j s. The ratio was constant for Cx37/Cx45 GJs at different V_j s, but was not the case for Cx37/Cx43 GJ, which showed an increase with V_j for the initial conductance ratio, but a decrease for the end conductance ratio.

One of the Cx37/Cx43 cell pairs showed one functional GJ channel to allow us to study single channel currents (i_{js}) at different V_{js} . All point histograms and Gaussian fits were used to measure the amplitudes of i_{js} for the main conducting state (the main open state). Various levels of subconductance states were also observed (Figure 2-6A, B). The plot of $i_{j} - V_j$ did not follow a simple linear regression with both V_j polarities and showed inward rectification similar to that of macroscopic $I_j - V_j$ plot for Cx37/Cx43 GJs (Figure 2-6C). Rectification was observed as there was a change in I_j with increasing V_{js} due to a change in channel conductance or resistance. The gap junctional unitary conductance (γ_j) of the main open state showed some interesting features. First, when Cx43 with $-V_j$ (or Cx37 with $+V_j$) the $\gamma_{j(-)}$ is larger than the γ_j of opposite V_j polarity, $\gamma_{j(+)}$. Second, both $\gamma_{j(-)}$ and $\gamma_{j(+)}$ were not constant at different V_j levels. The $\gamma_{j(-)}$ increased with the increase of V_j values, while the $\gamma_{j(+)}$ decreased with the increase of V_j values. Third, the ratio of $\gamma_{j(-)}/\gamma_{j(+)}$ appeared to increase with V_j values in a linear fashion (Figure 2-6C), again similar to what observed for the macroscopic $G_{j(-)}/G_j (+)$ ratio changes with V_j . More experiments are needed to have proper statistical analysis to confirm these interesting properties of Cx37/Cx43 GJ channels.

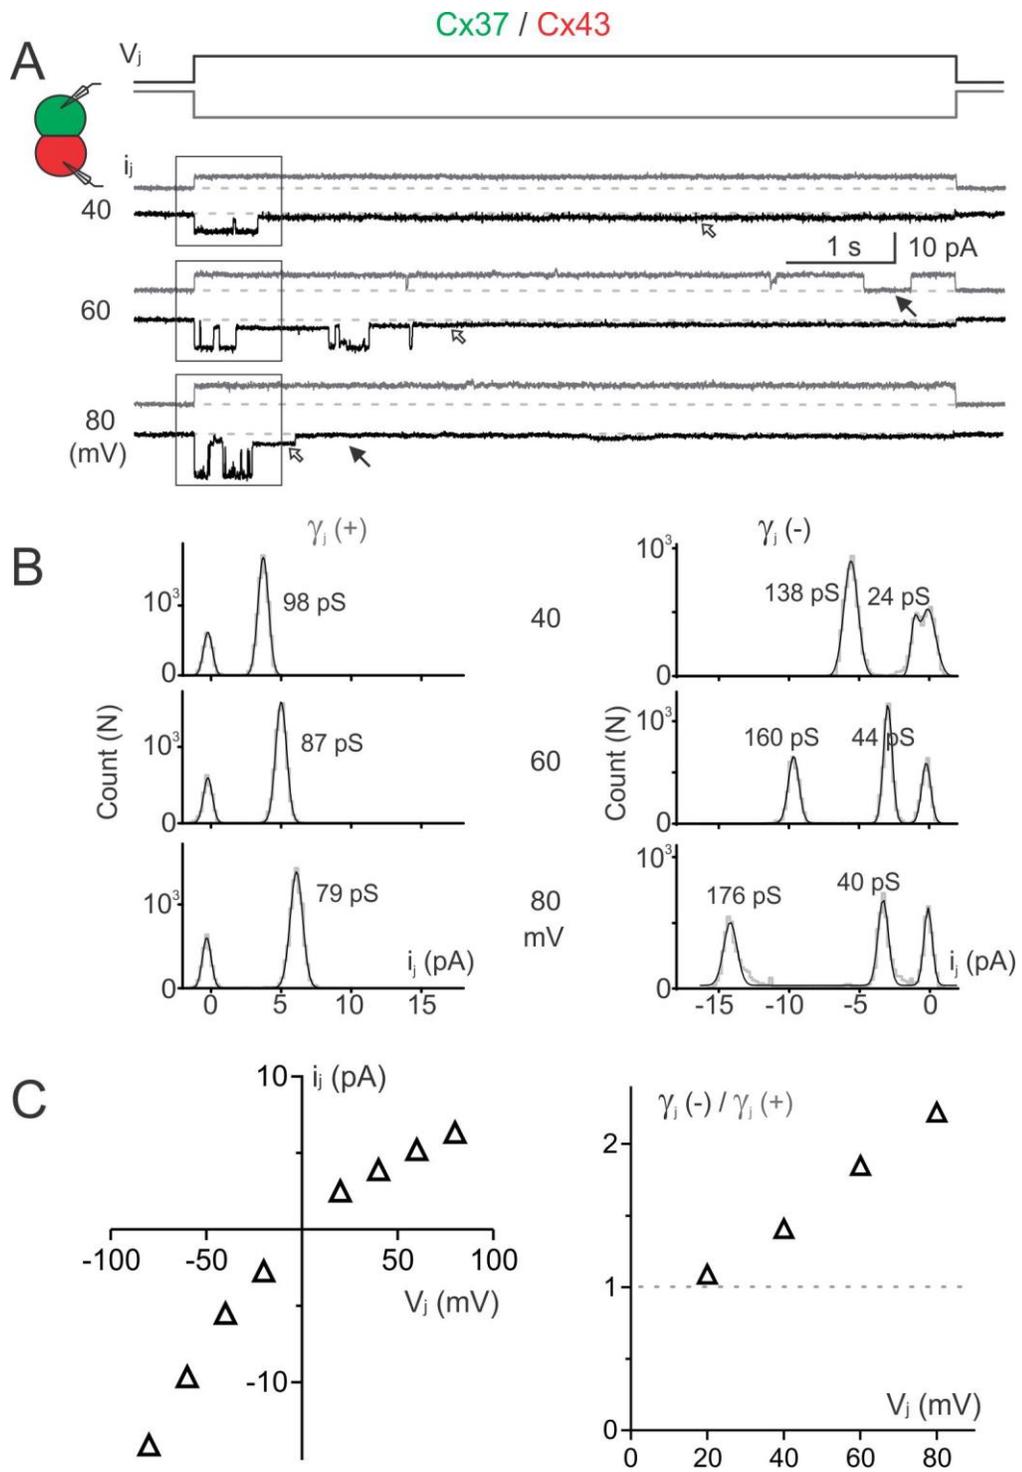

Figure 2-6

Figure 2-6. Unitary channel properties of heterotypic Cx37/Cx43 GJ.

(A) Single channel currents (i_j s) were recorded from a heterotypic Cx37/Cx43 cell pair at the indicated V_j s. (B) All point histograms were generated at the boxed areas shown in panel A. Gaussian fits were used to determine the i_j amplitudes of main open state and the subconductance states. (C) $i_j - V_j$ relationship of this heterotypic Cx37/Cx43 GJ was constructed and showed inward rectification. Right panel is the ratio of $\gamma_j(-)/\gamma_j(+)$ - V_j relationship for this GJ. It appeared that the ratio is increased with V_j in a linear fashion.

2.4.5 Characterization of V_j -gating of heterotypic Cx37/Cx45 GJs with prolonged V_j pulses

Heterotypic Cx37/Cx45 GJs showed a prominent V_j -gating when positive voltages were administered to the Cx37 cell (or Cx45 cell with $-V_j$) and an apparent reverse V_j -gating on the opposite V_j polarity. To further evaluate the minimum level of V_j s showing V_j -gating or reverse V_j -gating, we recorded I_{js} in response to much longer V_j pulses (duration = 15 seconds) and longer inter pulse intervals (15 seconds) to allow recovery of deactivated GJs (Figure 2-7A). We focused on very low V_j levels from ± 2 to ± 20 mV. As shown in Figure 2-7B, the threshold V_j for the normalized steady state conductance ($G_{j,ss}$) significantly below one (or displaying V_j -gating) was -5 mV (on Cx45 cell) and the threshold V_j for $G_{j,ss}$ higher than one (or the reverse V_j -gating) was $+10$ mV (on Cx45 cell). We believe that these values are under estimated as we only used a 15 seconds voltage pulse, which appeared to be not sufficiently long to reach a full steady state. As previously described in Figure 2-5B, the I_{js} of heterotypic Cx37/Cx45 displayed similar rectifications at lower V_j s (analysis not included in the figure). The ratio of the junctional conductance $G_{j(-)}/G_{j(+)}$ for both the $I_{j,ini}$ and $I_{j,end}$ were plotted with the absolute V_j s. However at lower V_j s, the ratio $G_{j(-)}/G_{j(+)}$ of Cx37/Cx45 increased with increasing V_j s ($P < 0.01$ for the initial and $P < 0.05$ for the end) (analysis not included in the figure).

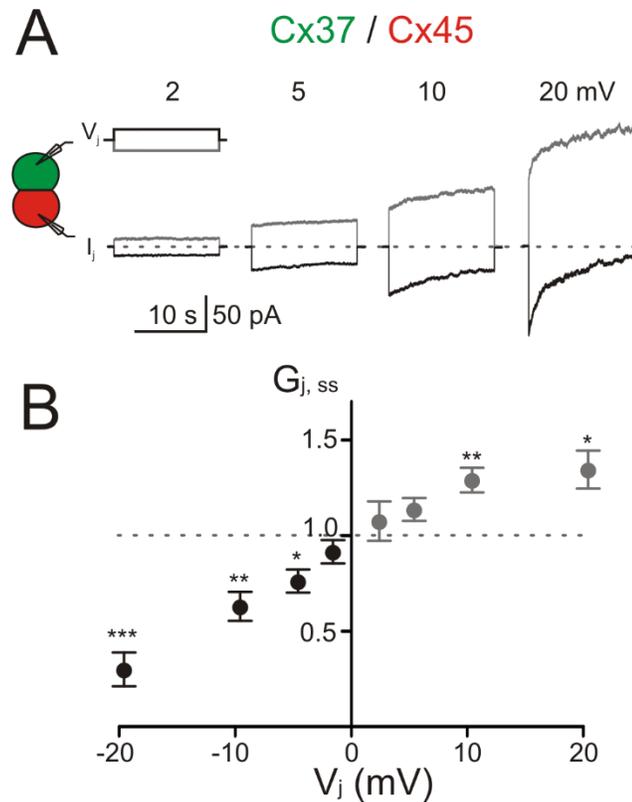

Figure 2-7. Long voltage pulse protocol revealed the threshold of heterotypic Cx37/Cx45 GJ V_j -gating.

(A) I_j s were recorded in response to a 15 second V_j -protocol from ± 2 , ± 5 , ± 10 , and ± 20 mV (as indicated above) for heterotypic Cx37/Cx45 cell pairs. The grey colored I_j s correspond to $-V_j$ on Cx37 cell or $+V_j$ on Cx45 cell. While black colored I_j s correspond to $+V_j$ on Cx37 cell or $-V_j$ on Cx45 cell. (B) Normalized $G_{j,ss}$ of Cx37/Cx45 GJ were plotted to the respective V_j s (defined by Cx45 cells). A significant reduction of $G_{j,ss}$ during a V_j pulse was observed at -5 mV ($p < 0.05$), increased V_j s (-10 and -20 mV) showed more reduction of $G_{j,ss}$ ($p < 0.01$ for both V_j s). On the other hand, reverse gating was observed as early as +10 mV leading to a significant increase in $G_{j,ss}$ ($p < 0.01$). $G_{j,ss}$ average values were compared to one (the grey dotted line) using a one-sample t-test.

2.4.6 Establish gap junction coupling of Cx37/Cx40 by designed docking variants

Sequence alignment and homology modeling of Cx40 GJs revealed several key residues at the docking interface (for example, D55 on the E1 and P193 on the E2 domain) could restrict its ability to dock with other connexins. Designed Cx40 variants, D55N or P193Q, have been shown to successfully rescue the ability of Cx40 to dock with Cx43 and Cx45 (Jassim et al., 2016; Ye et al., 2017). To test if these residues in Cx40 are also responsible for its failure in forming functional heterotypic Cx37/Cx40 GJs, heterotypic Cx37/Cx40 D55N (or Cx37/Cx40 P193Q) cell pairs were selected for dual patch clamp analysis. As shown in Figure 2-8, majority of heterotypic Cx37/D55N or Cx37/P193Q cell pairs formed functional GJs. The coupling percentages of both Cx37/D55N and Cx37/P193Q were similar to those of homotypic Cx37 or Cx40, but were significantly higher than that of Cx37/Cx40 cell pair ($p < 0.05$, Figure 2-8B). Similarly, the G_j of heterotypic Cx37/D55N (or Cx37/P193Q) GJs was significantly higher than that of Cx37/Cx40 and was similar to those of homotypic Cx37 or Cx40 GJs (Figure 2-8C). Significantly increased coupling% and G_j of Cx37/D55N or Cx37/P193Q than those of Cx37/Cx40 demonstrated that these Cx40 variants were fully capable of docking with Cx37 to form functional heterotypic GJs. The V_j -gating of Cx37/D55N or Cx37/P193Q GJs was largely symmetrical similar to those of homotypic Cx37 and Cx40 GJs (Figure 2-9A). $G_{j,ss} - V_j$ plots were constructed and the data were fitted well with Boltzmann equations for both V_j polarities (Figure 2-9B). The Boltzmann fitting parameters (Table 2-1) were similar to those of Cx37 or Cx40 GJs with only one consistent change for both variants, a lower V_0 values than those of Cx40 GJ when Cx37 cell with $-V_j$ s (or Cx40 variants with $+V_j$ s).

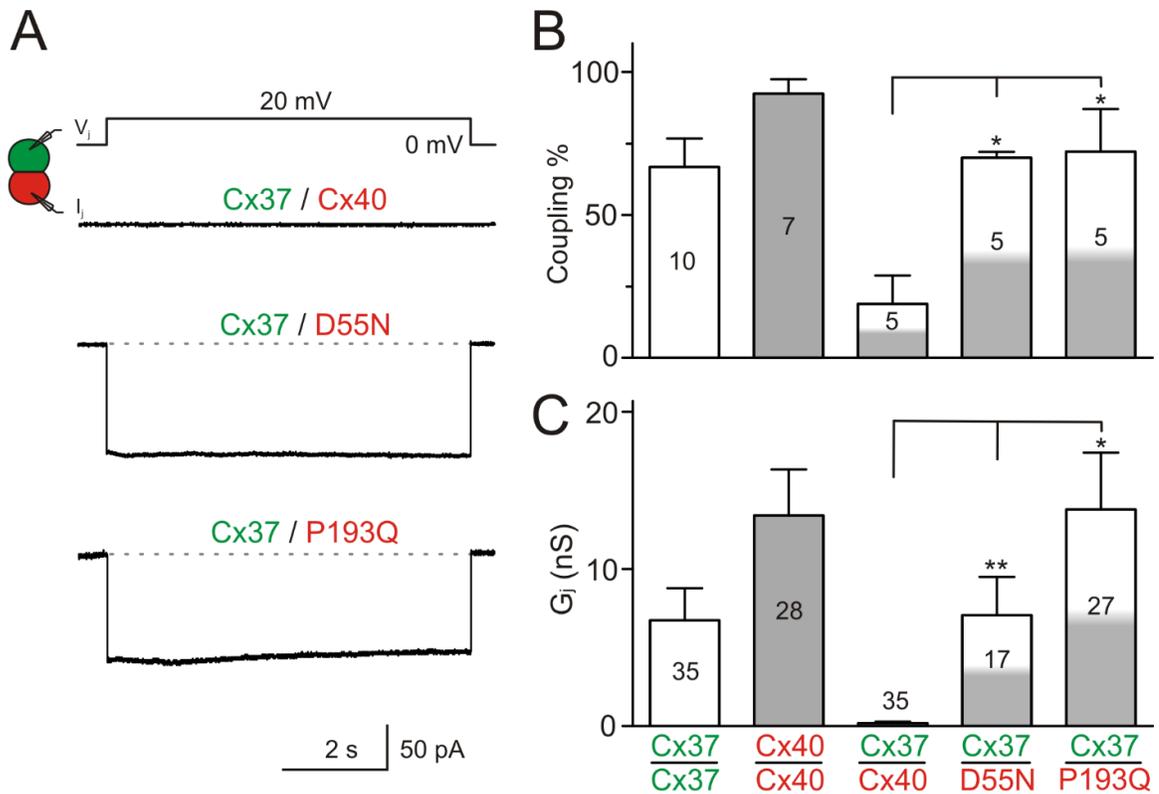

Figure 2-8. Coupling percentage and G_j of heterotypic GJs of Cx37 with Cx40 mutants.

(A) Representative I_j s were recorded from heterotypic Cx37/Cx40 D55N (Cx37/D55N) or Cx37/P193Q cell pairs in response to +20 mV V_j pulse. (B) Bar graph summarizes the coupling% of heterotypic Cx37/Cx40, Cx37/D55N, and Cx37/P193Q GJs. Both Cx37/D55N and Cx37/P193Q showed a significant increase in the coupling% compared to that of Cx37/Cx40 ($p < 0.05$). The total number of independent transfections is indicated. (C) Bar graph illustrates the averaged G_j of different cell pairs as indicated. A significant increase in G_j was observed for both Cx37/D55N and Cx37/P193Q cell pairs compared to that of Cx37/Cx40 ($p < 0.01$). The total number of recorded cell pairs is indicated. Data for homotypic Cx37 and Cx40 GJs were identical as those presented in Figure 2-1 for easy comparison.

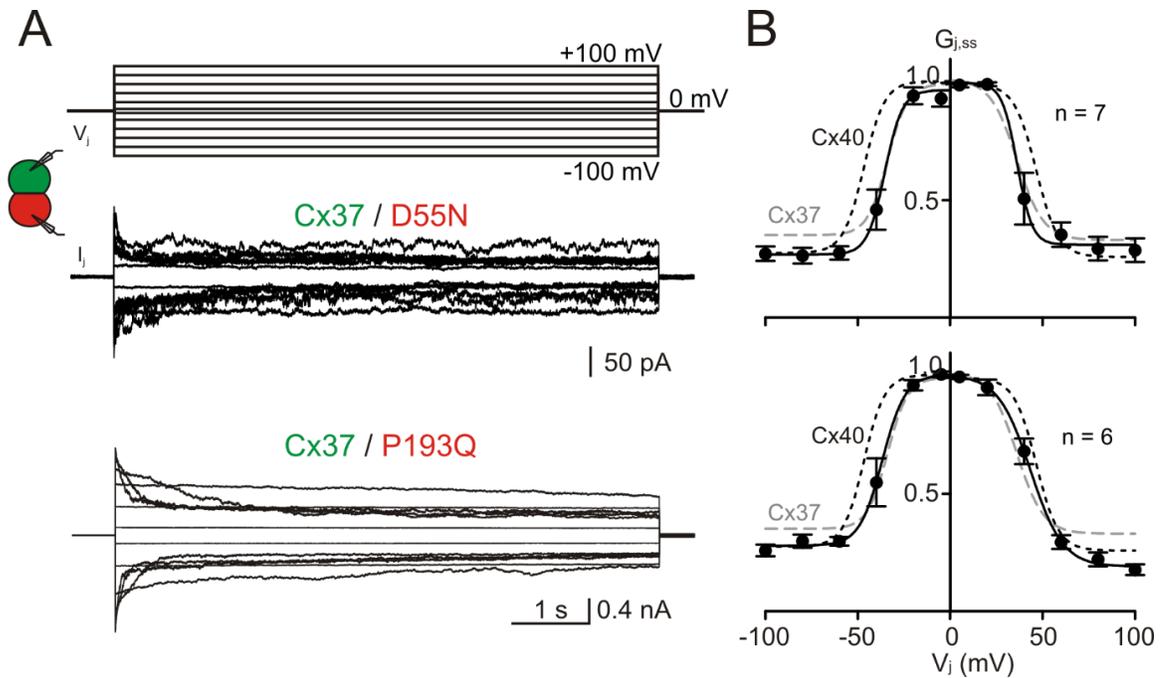

Figure 2-9. V_j -gating of heterotypic Cx37/D55N and Cx37/P193Q GJs.

(A) Superimposed I_j s were recorded from heterotypic Cx37/D55N or Cx37/P193Q GJs in response to a series of V_j pulses as indicated. (B) Normalized $G_{j,ss}$ of heterotypic Cx37/D55N or Cx37/P193Q (black filled circles) were plotted to different V_j s. $G_{j,ss} - V_j$ plots were fitted well with Boltzmann equations for each V_j polarity (smooth black lines). Boltzmann fitting curves for Cx37 GJ (smooth grey dashed lines) and Cx40 GJ (smooth black dashed lines) were superimposed for easy comparison.

Table 2-1. Boltzmann Fitting parameters for homotypic and heterotypic GJs

| | V_j Polarity [†] | G_{min} | V_0 | A |
|------------------------------|--------------------------------|------------------------------------|----------------------------------|-----------------|
| Cx37 (n = 5) | + | 0.33 ± 0.03 | 36.1 ± 2.6 | 0.14 ± 0.05 |
| | - | 0.35 ± 0.03 | 33.9 ± 3.2 | 0.18 ± 0.08 |
| Cx40 (n = 7) | + | 0.26 ± 0.03 | $46.7 \pm 1.9^*$ | 0.17 ± 0.04 |
| | - | 0.28 ± 0.02 | $46.6 \pm 1.7^{**}$ | 0.18 ± 0.04 |
| Cx45 (n = 4) | + | $0.12 \pm 0.03^{***}$ | $24.6 \pm 2.2^*$ | 0.12 ± 0.03 |
| | - | $0.13 \pm 0.03^{***}$ | 29.9 ± 2.2 | 0.13 ± 0.02 |
| Cx37 / Cx43 (n = 4) | + | 0.18 ± 0.13 | $55.8 \pm 7.3^*$ | 0.06 ± 0.03 |
| Cx37 / Cx45 (n = 5) | + | $0.06 \pm 0.02^{***}$ (w/ Cx37) | $24.5 \pm 1.3^{**}$ (w/ Cx37) | 0.12 ± 0.01 |
| Cx37 / Cx40 D55N (n = 7) | + | 0.31 ± 0.03 | 36.3 ± 4.3 | 0.24 ± 0.26 |
| | - | 0.27 ± 0.02 | $35.4 \pm 2.7^*$ (w/ Cx40) | 0.21 ± 0.11 |
| Cx37 / Cx40 P193Q (n = 5) | + | $0.19 \pm 0.02^*$ (w/ Cx37) | 43.6 ± 1.5 | 0.11 ± 0.02 |
| | - | 0.28 ± 0.03 | $36.7 \pm 2.0^{**}$ (w/ Cx40) | 0.16 ± 0.06 |

Data are presented as mean \pm SEM and V_0 are absolute values. One-way ANOVA followed by Tukey post-hoc test was used to compare Boltzmann fitting parameters of the homotypic and heterotypic GJs against the respective controls with the same V_j polarity. Student *t*-test was used to compare Boltzmann fitting parameters of Cx37/Cx43 GJ with those of Cx37. The number of asterisks indicate the statistical difference level (* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$).

$\dagger V_j$ polarity of heterotypic GJs is defined by the relative voltage level of Cx37-expressing cell.

2.5. Discussion

The present study is the first to investigate the functional status and channel properties of human Cx37 with Cx40, Cx43, or Cx45 heterotypic GJs. The results showed that the coupling status and G_j of both heterotypic Cx37/Cx43 and Cx37/Cx45 GJs were comparable to the respective homotypic controls. However significant lower coupling% and low G_j were observed for heterotypic Cx37/Cx40 cell pairs. Based on these observations, Cx37 was able to form heterotypic GJ channels with Cx43 and Cx45 but not with Cx40. Characteristics including asymmetric V_j -gating and I_j rectifications were observed with both Cx37/Cx43 and Cx37/Cx45. Cx37/Cx43 GJs displayed V_j -dependent deactivation with both V_j polarities. On the other hand, Cx37/Cx45 GJs exhibited strong deactivation with $-V_j$ s administered to the Cx45 cell and reverse gating with $+V_j$ s. Interestingly, the I_j - V_j plot of Cx37/Cx43 GJ showed continuous voltage dependent I_j rectification however I_j - V_j plot rectification of Cx37/Cx45 GJ was only at $V_j = 0$ mV was not. Current rectification was observed within the preliminary single channel currents of Cx37/Cx43 as the ratio of $\gamma_j(-)/\gamma_j(+)$ appeared to increase with V_j values in a linear fashion. But more experiments with proper statistical analysis are required to confirm this. A longer V_j pulse protocol was designed for Cx37/Cx45 to closely examine the V_j -dependent deactivation at lower voltages (Figure 2-7). The reduction in $G_{j,ss}$ occurred when a V_j pulse of -5 mV was applied to the Cx45 cell whereas an increase was observed at +10 mV. Finally to change the low probability of coupling% and G_j , two previously engineered Cx40 variants, D55N and P193Q, were able to form functional heterotypic GJs with Cx37.

The relevance of the present study is to help understand the different types of GJs that can potentially form with human connexin37 as each cell type is capable of expressing

more than one connexin. The present study demonstrated that functional channels can respond differently to subtle voltage changes and exert unique channel properties. Overall this would reflect the different GJ channels throughout the vasculature between ECs, VSMCs, and even at the myoendothelial junction. Although the signaling cascade to maintain vasomotor tone may originate either from the EC or VSMC side, GJs are important within the vasculature to help facilitate low resistance passage in signal conduction both electrically and metabolically.

2.5.1 Physiological role of vascular connexins

The maintenance of vasomotor tone is crucial in the vasculature in order to accommodate various blood flow and pressure. Through GJs, electrical signals are propagated through interconnected cells, either homocellularly or heterocellularly, to coordinate spontaneous diameter changes in blood vessels (Haddock and Hill, 2005). Mouse models with vascular connexin gene KOs assisted researchers in understanding the important role these genes possess in the structural integrity and function of blood vessels. Kruger and colleagues observed several developmental traits were impaired in Cx45 KO mice including the transformation of mature vessels, formation of vascular trees in the yolk sac, and smooth muscle layer development around major arteries (Kruger et al., 2000). As apoptosis was observed in virtually all tissues, death was imminent in the early embryonic stages (E9.5 to E10.5) (Kruger et al., 2000). For Cx43 KO mice, they died at birth due to the obstruction of the right ventricular outflow tract (Reaume et al., 1995). Moreover even the loss a single allele demonstrated defects in the patterning of coronary arteries (Clauss et al., 2006). The KO of the Cx43 gene appeared to alter the cell signaling pathways regulating vasculogenesis and angiogenesis as several genes associated with differentiation and

function of vascular cells were modified (Walker et al., 2005). On the other hand, mice were viable from the individual Cx40 or Cx37 KOs and considered as non-lethal. Cx40 KO mice embryos displayed small defects along the cardiac septum and predisposition towards arrhythmias (Figuroa and Duling, 2009; Kirchhoff et al., 1998). Interestingly, no vascular abnormalities including heart dysfunction were observed with Cx37 deficient mice except that females were reported to be infertile (Simon et al., 1997). Interestingly a double KO of Cx37 and Cx40 was discovered to be lethal as mice died around birth because of several vascular abnormalities with susceptibility to vasodilatations (Simon and McWhorter, 2003).

2.5.2 A group of docking compatible connexins

As each cell type in the vasculature can express more than one connexin isoform, co-expression can also lead to the potential formation of heterotypic GJ channels including heteromeric heterotypic (Sohl, 2004). Homomeric heterotypic GJs were focused in the present study as it was easier to control the connexin expression and docking of hemichannels. According to studies on docking-compatible connexins with Cx37, the heterotypic GJs are Cx37/Cx40, Cx37/Cx43, and Cx37/Cx45 which can potentially form intercellular connections between ECs and EC-VSMCs (Bai, 2016; Elfgang et al., 1995; Hill et al., 2002; van Kempen and Jongasma, 1999). The coupling characteristics, G_j , and V_j -gating parameters of human homotypic GJs in the present study have all been previously characterized (Barrio et al., 1997; Gonzalez et al., 2007; Jassim et al., 2016; Noureldin et al., 2018; Reed et al., 1993; Veenstra et al., 1994; Ye et al., 2017). Compared to the other vascular connexins, Cx45 GJs notably displayed the strongest and fastest V_j -dependent deactivation as reported in the literature (Barrio et al., 1997; Ye et al., 2017). For Cx37, the

present electrophysiological study showed approximately a little over 60% of the cell pairs were coupled as previously reported (Reed et al., 1993; Veenstra et al., 1994); although other parameters including average G_j , G_{\min} , V_0 , and A were slightly higher.

Reported in previous studies as heterotypic GJs are composed of different connexin hemichannels, the G_{jss} - V_j relationship for both V_j polarities will be asymmetric which was consistent with the asymmetric V_j -gating of heterotypic Cx37/Cx43 and Cx37/Cx45 GJs (Barrio et al., 1991; Jassim et al., 2016; Ye et al., 2017). In the contingent gating model, it has been proposed that a GJ channel possesses two gates in series (one per hemichannel) and the gating state of one hemichannel can influence the voltage applied on the other hemichannel (Harris et al., 1981). In other words, a large V_j could affect one of two gates driving the GJ channel to a reduced subconducting or closed state. For homotypic Cx45 GJs, the V_j -gating polarity is known to be negative meaning that V_j -gating closes the hemichannel at $-V_{js}$ (Chen-Izu et al., 2001). Furthermore as the unitary channel conductance (γ_j) of Cx45 GJ (32-38 pS) is much lower than the γ_j of Cx37 (300 pS) (Elenes et al., 2001; Veenstra et al., 1994), most of the administered V_{js} on a heterotypic Cx37/Cx45 GJ would be on the docked Cx45 hemichannel and make the GJ prone to close when $-V_j$ is on the Cx45 cell. This is consistent with data as heterotypic Cx37/Cx45 GJs displayed noticeable and fast V_j -dependent deactivation when $-V_{js}$ were applied on the Cx45 cell (or Cx37 cell with $+V_{js}$) which indicated that Cx37/Cx45 follows the contingent gating model. Detailed Boltzmann fitting of the V_j -gating properties of Cx37/Cx45 GJ revealed no significant changes for the G_{\min} , slope A and V_0 , but the G_{\min} was about half of those observed for homotypic Cx45 GJs. On the other hand there was a significant decrease for G_{\min} and V_0 , but the slope A was similar to those observed for homotypic Cx37.

Heterotypic Cx37/Cx45 GJs was further investigated due to their distinct V_j -gating profile and potentially modelled EC-VSMC connections via the MEJ. Although studies have reported the membrane potentials (V_m) of ECs and VSMCs to be identical (Emerson and Segal, 2000; Welsh and Segal, 1998), a noticeable change in I_j occurred within a narrow V_j range (-5 mV to +10 mV) between the cell pair. This experiment suggested if EC-VSMCs are coupled by heterotypic Cx37/Cx45 GJs, then the GJs would be modulated by small voltage differences between these two cell types. Although at small V_j s (± 2 to ± 20) the I_j - V_j plot of Cx37/Cx45 displayed similar features to the I_j - V_j plot at large V_j s (± 20 to ± 100), the ratio $G_j(-)/G_j(+)$ of Cx37/Cx45 were found to be V_j dependent at small V_j s. It is difficult to make comparisons on the responses of Cx37/Cx45 at different sets of V_j s as different experimental conditions were used during the administration of small or large V_j s. Among the four human connexins studied, the V_j -gating polarity for Cx45 is known (Chen-Izu et al., 2001) however the V_j -gating polarities of Cx37, Cx40, and Cx43 have not been clearly identified and have been based on their corresponding rodent connexins (e.g. mouse or rat) (Bruzzone et al., 1994; Hennemann et al., 1992; Valiunas et al., 2001; White et al., 1994). The V_j -gating polarity of Cx37 was difficult to determine with homotypic GJ channels because of the symmetry in its V_j -gating profile (Hennemann et al., 1992). In comparison to Cx37/Cx45, the consistent characteristic of pronounced and fast V_j -dependent deactivation when $-V_j$ s were applied on the Cx45 cell (or $+V_j$ s on Cx37 cell) indicated that the V_j -gating polarity of Cx37 was positive. For Cx43, the V_j -dependent deactivation of heterotypic Cx37/Cx43 GJs occurred when $+V_j$ s were applied on the Cx43 cell (or $-V_j$ s on Cx37 cell) indicating that V_j -gating polarity of Cx43 was also positive. Further evidence is seen in another study with the asymmetric V_j -gating of heterotypic

Cx43/Cx45 as V_j -dependent deactivation was observed with $+V_j$ s on Cx43 cell (or $-V_j$ s on Cx45 cell) (Ye et al., 2017). In a previous mutational study of Cx26 and Cx32 hemichannels, Verselis and colleagues explained that the V_j -gating polarity of these connexins can be determined by the presence of a charged residue at the 2nd or 3th position of the NT domain (D2) (Verselis et al., 1994). In other words a connexin with a negatively charged residue at 2nd or 3th position (D2), would close the hemichannel at a $+V_j$ polarity whereas the absence of the negatively charged residue would close the hemichannel at a $-V_j$ polarity (Verselis et al., 1994). Amino acid sequence alignment of Cx37, Cx40, Cx43, and Cx45 with Cx26 in the NT domain showed that these connexins except Cx45 contained an aspartic acid at 2nd or 3th position; which is consistent with our prediction. Although V_j -gating was not observed with Cx37/Cx40, it is speculated that Cx40 hemichannel, too, possess a positive V_j -gating polarity based on the explanation above and from the V_j -gating of the designed Cx40 variants. Furthermore the γ_j of Cx43 GJ (60- 100 pS) is lower than the γ_j of Cx37 (300 pS) (Fishman et al., 1991; Veenstra et al., 1994). Based on the V_j -gating polarity of Cx43, most of the applied V_j s on a heterotypic Cx37/Cx43 GJ would be on the docked Cx43 hemichannel and making the GJ likely to close when $-V_j$ is on the Cx43 cell. This is consistent with data as heterotypic Cx37/Cx43 GJs displayed fast V_j -dependent deactivation when $-V_j$ s were administered on the Cx43 cell which indicated that Cx37/Cx43 also follows the contingent gating model. Detailed Boltzmann fitting of the V_j -gating properties of Cx37/Cx43 GJ revealed significant increase for V_0 but the slope A and G_{\min} were lower than those observed for homotypic Cx37 GJs.

2.5.3 Single Channel Analysis of Cx37/Cx43 GJ

The single channel study of Cx37/Cx43 GJ is the first for human Cx37. The preliminary data showed multiple (main open, one or more subconductance, and fully closed) states as well as different gating transitions over time between the Cx37 hemichannel and Cx43 hemichannel suggesting the two V_j -gating mechanisms (fast V_j -gating and slow V_j -gating). Fast V_j -gating is defined by the rapid transition time (<1 – 2 mS) from a main open state to a subconductance state and slow V_j -gating is defined by the slow transition time (generally tens of milliseconds) from a main open or subconductance state to a fully closed state (Bukauskas and Verselis, 2004; Bukauskas and Weingart, 1994; Xin et al., 2010). With $-V_j$ s on Cx43 hemichannel (or Cx37 with $+V_j$ s), the GJ channel displayed gating transitions between all three states indicating the presence of both fast and slow V_j -gating (Figure 2-6 panel A). Meanwhile with the opposite V_j polarity, only transitions between two (main open and closed) states were observed indicating slow V_j -gating (Figure 2-6 panel A). In a previous study, Elenes and colleagues investigated single channel studies on heterotypic rCx43/mCx45 GJ channel. Despite the use of non-human connexins, a similar observation was made when $-V_j$ s were applied to the rCx43 side in which all the gating transitions were between the main open state and the fully close state (Elenes et al., 2001). They explained that with the heterotypic docking of rCx43 and mCx45 hemichannels, the fast V_j -gating of rCx43 seemed to disappear; similar to what was observed in the present study.

2.5.4 Cx40 hemichannel does not dock with Cx37 hemichannel

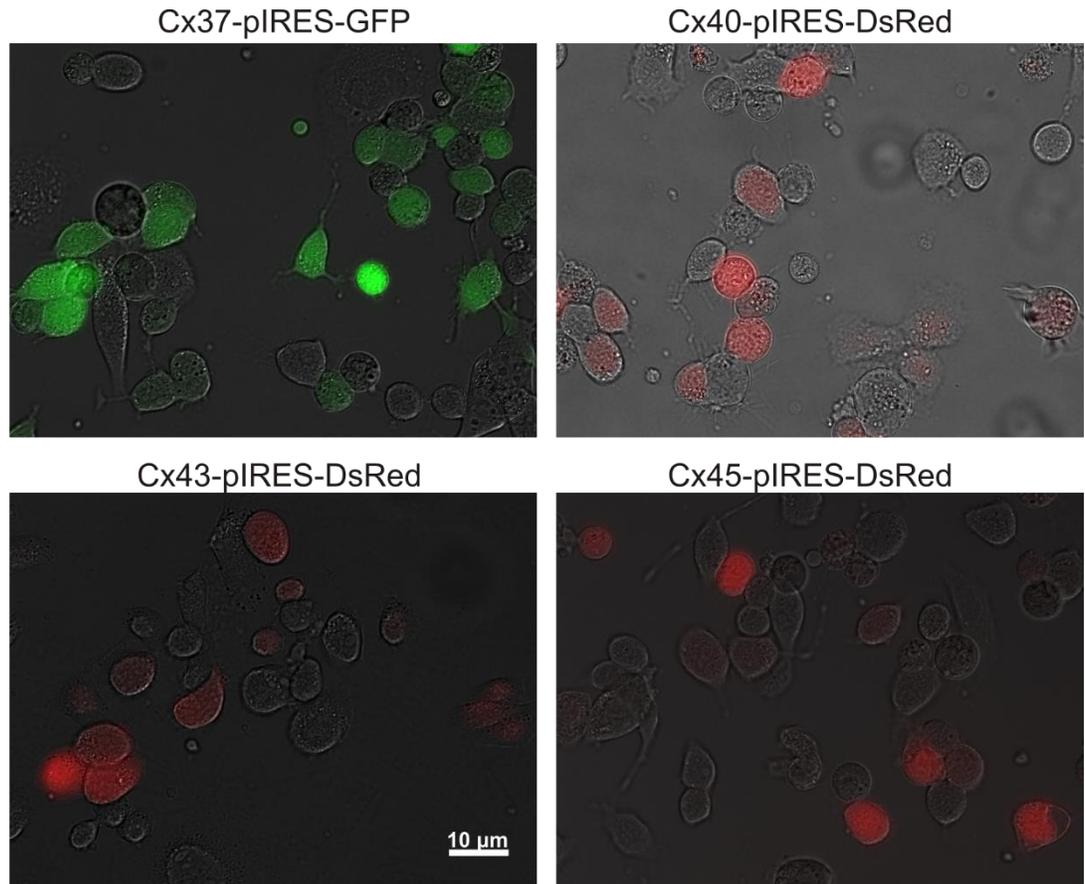

To our surprise, most heterotypic Cx37/Cx40 cell pairs were not coupled, and even the pairs that showed coupling exhibited very low level of G_j . As we used a transient

expression system, the connexins under study tend to be overexpressed and therefore likely to be an over representation of the actual heterotypic interaction. It is speculated that under physiological conditions, the probability of these two connexins to form heterotypic GJs could be even lower. Jassim and colleagues aligned both the E1 and E2 amino acid sequences of Cx40 and Cx43 with Cx26 as a reference which later incorporated Cx45 (Jassim et al., 2016; Ye et al., 2017). Although the three cysteine residues in each domain were conserved, Cx40 possessed a few different amino acids at the docking interface; two of which were associated with hydrogen bonds (HBs). In the 55th and 193rd positions of Cx40 were aspartic acid and proline respectively. Based on Cx40 homology model, aspartic acid contained a negative side chain that contributed to electrostatic repulsion with two nearby Cx43 residues (Jassim et al., 2016). Meanwhile the cyclic side chain of proline restricted the E2 domain to an incompatible formation with Cx43 E2 (Jassim et al., 2016). By mutating the residue, D55N or P193Q, the electrostatic repulsion or steric interference were eliminated respectively and HB interactions improved, which might have played a role in rescuing the heterotypic coupling between Cx40 with other connexins as also noticed in the current study. In the literature, it has been well documented that mCx37 can form functional heterotypic GJs with mCx40 as they belong in the same group of docking-compatible connexins (Bruzzone et al., 1993; Elfgang et al., 1995; White et al., 1995). However the present study is the first to demonstrate that this interaction is not the case through human connexins. With the collection of previous investigations including the present study, it is argued that amongst human connexins, Cx40 may not belong in the same group of docking compatible connexins (Jassim et al., 2016; Ye et al., 2017).

2.5.5 Conclusion

The ability of human Cx37 to form heterotypic GJs with other human connexins such as Cx40, Cx43, and Cx45 have not been established in the past. The present study provided experimental evidence that Cx37 hemichannel can dock with Cx43 or Cx45 hemichannels to form functional heterotypic GJs but not with Cx40 hemichannels. The formation of heterotypic Cx37/Cx43 and Cx37/Cx45 GJs exhibited distinct characteristics including asymmetric V_j -gating and I_j rectifications at different V_j polarities. It has been previously established that both the E1 and E2 domains are crucial for the non-covalent interactions between two docked hemichannels. Mutating the residue, D55N or P193Q, in WT Cx40 rescued the heterotypic interaction with Cx37. Human Cx40 showed docking incompatibility with Cx43, Cx45, and Cx37 indicating that Cx40 is not docking compatible with many in this group of connexins and may be better removed from this docking compatible group.

2.6. Supplemental Material

Supplemental Figure 2-1. Fluorescence microscopy images superimposed with DIC of transfected N2A cells.

N2A cells were transfected with Cx37-IRES-GFP (or Cx40, Cx43, Cx45, each of them in IRES-DsRed vector). Prior to performing dual whole cell patch clamp, the cell confluency on the glass coverslips were around 60-70% and majority of the cells fluoresced for each respective transfection. For heterotypic GJ studies, Cx37-IRES-GFP transfected cells were mixed with cells transfected with Cx40-IRES-DsRed, Cx43-IRES-DsRed, or Cx45-IRES-DsRed to allow formation of heterotypic cell pairs.

3. Discussion

3.1 Overall Study

The present study aimed to address the gap in knowledge on the functional status of heterotypic GJs and their channel properties of human vascular connexins specifically the heterotypic docking compatibility of human Cx37 with Cx40, Cx43 and Cx45. Accumulated experimental evidence in the heterotypic docking compatibility of mouse connexins is mostly true for human connexins but with a few exceptions especially on Cx40 (Brink et al., 1997; Elfgang et al., 1995; Jassim et al., 2016; Ye et al., 2017). Electrophysiological recordings showed that heterotypic Cx37/Cx43 and Cx37/Cx45 displayed comparable coupling status and G_j to their respective homotypic GJ controls. Interestingly, heterotypic Cx37/Cx40 cell pairs exhibited low coupling status and G_j . From heterotypic Cx37/Cx43 and Cx37/Cx45 GJs recordings, asymmetric V_j -gating and I_j rectifications were characteristics commonly observed. Cx37/Cx43 GJs displayed V_j -dependent deactivation with both V_j polarities. On the other hand, Cx37/Cx45 GJs exhibited strong channel deactivation with $-V_j$ s administered to the Cx45 cell and reverse gating in the opposite V_j polarity. A possible explanation for this observation could be attributed by the negative V_j -gating polarity of Cx45 hemichannels. The I_j rectification of Cx37/Cx43 appeared to be voltage dependent and was continuously observed within the preliminary single channel analysis of Cx37/Cx43 as the ratio of $\gamma_j(-)/\gamma_j(+)$ appeared to increase with V_j values in a linear fashion. However I_j rectification of Cx37/Cx45 did not appear to be voltage dependent. After the application of a different V_j pulse protocol, it was revealed that heterotypic Cx37/Cx45 GJs can be modulated by few millivolt differences in the membrane potentials. Finally designed docking variants in Cx40 E1 or

E2 domains (D55N or P193Q respectively) successfully established heterotypic docking between Cx37 and Cx40. Overall, Cx37 was able to form heterotypic GJ channels with Cx43 and Cx45 but not with Cx40.

3.2 Limitations and future studies

To address the heterotypic formation of Cx37 with Cx40, Cx43 or Cx45, transfection of the respective cDNAs took place in N2A cells. This cell line is an excellent model system to study different connexins as these cell lines are GJ deficient, easily transfected with connexin cDNA, and easily used for functional characterization of GJs (Bai and Cameron, 2016). As mentioned before, several Cx43 expressing cell pairs exhibited very high G_j levels limiting the maintenance of proper voltage clamp and proper V_j -gating analysis could not be performed (data not shown). A GJ impermeable dye, Dextran Green (molecular weight 10,000 Da, 0.25 mg/mL in pipette solution), was occasionally implemented to ensure some of the highly coupled cell pairs were not caused by cytoplasmic bridges (Sun et al., 2013). If green dye was not seen in both cells, the high G_j was not attributed by cytoplasmic bridges (Sun et al., 2013). The V_j -gating analysis for Cx43 could be resolved with different experimental conditions by decreasing the amount of transfected DNA, reducing transfection time, or even shortening the replate time of the cells (Bai and Cameron, 2016). Due to stringent experimental conditions, it is speculated that the collected data is an over-representation of the homotypic and heterotypic coupling status. Physiologically, the probability of these two connexins to form heterotypic GJs could be even lower. Importantly these model cells are not native in the human body nor do they express all the native connexins concurrently. Although interconnected cell pairs can be coupled via homotypic and heterotypic GJs, there is added complexity of including

the possible formation of heteromeric heterotypic GJ channels (Valiunas et al., 2001). Studies have reported heteromeric GJ channels to be inconsistent with large variability in the G_j/V_j relationship and different from homotypic or heterotypic GJs (Brink et al., 1997; Valiunas et al., 2001). In respect to heterotypic GJs, it was mentioned that more experiments are required for the Cx37/Cx43 single channel study. It would be interesting to study if the gating transitions at different V_j polarities is consistent in different cell pairs. Likewise it would be intriguing to observe Cx37/Cx45 single channels on its gating transitions at different V_j polarities and if the voltage independent i_j rectification holds true as observed with macroscopic I_j recordings.

Furthermore a different V_j pulsing protocol was used in the present study containing a long pulsing duration (15 seconds) and long inter pulse intervals (15 seconds) for two reasons. First, Ye and colleagues fitted the V_j -gating process of homotypic Cx45 with a single exponential equation for the I_j s in response to V_j -pulses. The time constant (τ) of homotypic Cx45 GJs decreased with increasing V_j s and the τ - V_j relationship appeared to be linear on a semi-logarithmic plot (Ye et al., 2017). As a result, the pulsing duration of 7 seconds did not give the channel enough time to fully deactivate at low V_j s. Second, a pulsing interval of 15 seconds would ensure ample amount of time for the channels to fully recover from the previous V_j pulse (Ye et al., 2017). However after the application of the different protocol, a definitive steady state was not observed at -20 mV despite the lower $G_{j,ss}$ at this V_j . This indicated that a longer pulsing period may be required. With + V_j s on the Cx45 cell, reverse gating was observed as shown by the increasing $G_{j,ss}$. But it is not clear if the rising I_j s are influenced from the recovery of prior deactivated channels. To

address this concern, a V_j protocol (with the same inter pulse interval) that administers a set of V_j pulses (with identical polarity) at a time would be ideal.

3.3 Physiological role of vascular connexins from mice KOs

GJs have been found at cell junctions between endothelial cells (ECs), between vascular smooth muscle cells, and also at the myoendothelial junctions connecting the two cell types (de Wit et al., 2009; Figueroa and Duling, 2009). Vascular connexins (Cx37, Cx40, Cx43, and Cx45) can form various types of GJ channels to transfer electrical signals through interconnected cells and synchronize spontaneous diameter changes during vasodilation/constriction (Haddock and Hill, 2005). Most of our knowledge comes from studies on rodent connexin but the same vascular connexins also exist in humans. Collectively many studies directed the abundant expression of Cx37 and Cx40 in the ECs (Gabriels and Paul, 1998; van Kempen and Jongsma, 1999) while Cx43 and Cx45 in the VSMCs (Bruzzone et al., 1993; Little et al., 1995; Pogoda et al., 2014; Severs et al., 2001). However, expression of Cx43 and Cx37 have been reported in ECs and VSMCs to a lesser degree (Gabriels and Paul, 1998; Little et al., 1995; Rummery et al., 2002; Severs et al., 2001; van Kempen and Jongsma, 1999).

A considerable amount of studies have performed vascular connexin gene knockouts (KOs) in mice to highlight the importance of these genes physiologically. Cx45 KO mice demonstrated various impairment in blood vessel development and maturation resulting in death during the early embryonic stages (E9.5 to E10.5) (Kruger et al., 2000). Cx43 KO mice died due to the elimination of this connexin as the expression of genes regulating vascular cell differentiation and function were altered; affecting vasculogenesis and angiogenesis (Clauss et al., 2006; Reaume et al., 1995; Walker et al., 2005). Individual

Cx40 and Cx37 KO mice were considered non-lethal. Cx40 KO mice were susceptible towards arrhythmias and displayed little defects during heart development whereas Cx37 KO mice females suffered infertility (Figuroa and Duling, 2009; Kirchhoff et al., 1998; Simon et al., 1997). However for Cx37 and Cx40 double KO, mice died around birth because of several vascular abnormalities with susceptibility to vasodilatations (Simon and McWhorter, 2003).

3.4 Characterization of heterotypic GJs with Cx37

The majority of experimental evidence on the heterotypic docking compatibility of vascular connexins were on rodent connexins. Collectively this revealed that Cx37, Cx40, Cx43, and Cx45 belong to the same group of docking-compatible connexins and each were fully capable of forming heterotypic GJs with each other (Bai, 2016; Brink et al., 1997; Elenes et al., 2001; Elfgang et al., 1995; Hennemann et al., 1992; Rackauskas et al., 2007). However, studies on human vascular connexins revealed otherwise prompting the characterization of Cx37 and its heterotypic docking capabilities with Cx40, Cx43, or Cx45 (Jassim et al., 2016; Ye et al., 2017). All characteristics of homotypic GJs in the present study have been previously reported including the coupling status, G_j , and V_j -gating parameters (Barrio et al., 1997; Gonzalez et al., 2007; Jassim et al., 2016; Noureldin et al., 2018; Reed et al., 1993; Veenstra et al., 1994; Ye et al., 2017). The asymmetric macroscopic I_j recordings and G_{jss} - V_j relationship at both V_j polarities observed in Cx37/Cx43 or Cx37/Cx45 cell pairs are common characteristics for heterotypic GJs (Barrio et al., 1991; Elenes et al., 2001; Jassim et al., 2016; Ye et al., 2017). Although the V_j -gating polarity for homotypic Cx45 GJs has been determined to be negative, the V_j -gating polarities of Cx37, Cx40, and Cx43 have not been clearly identified and been based on

rodent variants (Bruzzone et al., 1994; Chen-Izu et al., 2001; Hennemann et al., 1992; Valiunas et al., 2001; White et al., 1994). Heterotypic Cx37/Cx45 GJs consistently displayed pronounced V_j -dependent deactivation at $-V_j$ s applied on the Cx45 cell (or $+V_j$ s on Cx37 cell) indicating the V_j -gating polarity of Cx37 was positive. In heterotypic Cx37/Cx43 cell pairs, V_j -dependent deactivation occurred at $+V_j$ s on the Cx43 cell as this was also observed in previous study which indicates that V_j -gating polarity of Cx43 was positive (Ye et al., 2017). Sequence alignment of Cx37, Cx40, Cx43, and Cx45 with Cx26 in the NT domain showed that these connexins except Cx45 contained a negatively charged residue at the 3th position (D3). As explained by Verselis and colleagues, the presence of a negatively charged residue at the 2nd or 3rd position can dictate the V_j -gating polarity (Verselis et al., 1994). Based on this explanation and V_j -gating from the designed Cx40 variants, it is speculated that Cx40, too, possess a positive V_j -gating polarity.

The unitary channel conductance (γ_j) of homotypic Cx37 GJ (300 pS) is higher than the γ_j of both Cx43 (60-100 pS) and Cx45 GJ (32-38 pS) (Elenes et al., 2001; Fishman et al., 1991; Veenstra et al., 1994). Most of the applied V_j s on a heterotypic Cx37/Cx45 GJ would be on the docked Cx45 hemichannel making the GJ susceptible to close when $-V_j$ is on the Cx45 cell. Whereas for heterotypic Cx37/Cx43 GJ, most of the applied V_j s would be on the docked Cx43 hemichannel and making the GJ likely to close when $-V_j$ is on the Cx43 cell. This is consistent with the data as heterotypic Cx37/Cx45 and Cx37/Cx43 GJs displayed V_j -dependent deactivation when $-V_j$ s were applied on the Cx45 cell (or Cx43 cell) indicating that both Cx37/Cx45 and Cx37/Cx43 follow the contingent gating model. The model describes a GJ channel possessing two gates aligned in series (one in each hemichannel). A large V_j could affect one of the two gates, driving the channel to a reduced

subconducting or close state and influencing the voltage applied on the other hemichannel (Harris et al., 1981). The membrane potential (V_m) of ECs and VSMCs in the human body have not been clearly stated but studies on animal models reported the V_m of ECs and VSMCs to be identical (Emerson and Segal, 2000; Welsh and Segal, 1998). In hamster feed arteries, Emerson and Segal observed that a small negative current injection into an EC resulted in V_j of -5 mV causing hyperpolarization and relaxation of VSMCs. Whereas a positive current injection of the same magnitude, resulted in V_j of +2 mV causing depolarization and constrictions of VSMCs (Emerson and Segal, 2000). This observation is complemented in the present study as V_j -gating of heterotypic Cx37/Cx45 cell pairs were modulated with just a few millivolts in the event of a hyperpolarization or depolarization. The preliminary single channel study is the first to characterize the channel properties of heterotypic Cx37/Cx43 GJs; specifically human connexins. With $-V_j$ s on the Cx43 hemichannel (or $+V_j$ s on Cx37 cell), the GJ channel displayed gating transitions between all three states suggesting that both fast and slow V_j -gating were present. On the other hand with $+V_j$ s, the channel displayed gating transitions only between two (main open and closed) states suggesting slow V_j -gating. As previously explained, fast V_j -gating is the rapid transition time ($<1 - 2$ mS) from a main open state to a subconductance state and slow V_j -gating is the slow transition time (generally tens of milliseconds) from a main open or subconductance state to a fully closed state (Bukauskas and Verselis, 2004; Bukauskas and Weingart, 1994; Xin et al., 2010). Similarly when investigating single channels of heterotypic rCx43/mCx45 GJs, although non-human connexins were examined, all the gating transitions were between the main open and the fully close states when $-V_j$ s were applied to the rCx43 hemichannel (Elenes et al., 2001). They interpreted that the fast V_j -

gating of rCx43 seemed to disappear with the heterotypic docking of rCx43 and mCx45 hemichannels (Elenes et al., 2001).

3.5 Cx40 hemichannel does not dock with Cx37 hemichannel

Despite the several heterotypic studies on rodent connexins, the present study is the first to report docking incompatibility from cell pairs forming human heterotypic Cx37/Cx40 GJs due to low coupling% and G_j (Bruzzone et al., 1993; Elfgang et al., 1995; Hennemann et al., 1992). Previous studies also reported low coupling% and G_j between the docking of Cx40 hemichannels with Cx43 hemichannels or Cx45 hemichannels (Jassim et al., 2016; Ye et al., 2017). Sequence alignment in both the E1 and E2 domains of Cx40, Cx43 and Cx45 with Cx26 revealed Cx40 to have a few different residues at the docking interface; two of which were associated with hydrogen bonds (HBs), D55 and P193 (Jassim et al., 2016; Ye et al., 2017). Cx40 homology model revealed that the negative side chain of D55 contributed to electrostatic repulsion with two nearby Cx43 residues and the cyclic side chain of P193 restricted the E2 domain to an incompatible formation with Cx43 E2 (Jassim et al., 2016). The heterotypic coupling between Cx40 with other connexins was rescued as also seen in the present study by mutating these residues to either D55N or P193Q which eliminated the electrostatic repulsion or steric interference respectively. With the difference between human and rodent connexins, it is suggested that human Cx40 may not belong in the same group of docking compatible connexins.

3.6 Summary

The goal of the present study was to address the functional status of heterotypic GJs and their channel properties of human vascular connexins specifically Cx37, Cx40, Cx43

and Cx45. From the literature, KO studies in mice have revealed the importance of vascular connexins in proper blood vessel development and function. Previous reports from the Bai lab indicated differences between mouse and human connexins in terms of their heterotypic docking compatibility (Jassim et al., 2016; Ye et al., 2017). Electrophysiological recordings revealed that Cx37 can form heterotypic GJs channel with Cx43 and Cx45 but not with Cx40. Cx37/Cx43 and Cx37/Cx45 GJs were further characterized for their asymmetric V_j -gating, I_j rectifications, and Boltzmann fitting parameters. Based on the data of the present study, the V_j -gating polarity of Cx37, Cx40 and Cx43 were predicted to be positive and it was suggested that Cx37/Cx43 and Cx37/Cx45 GJs both follow the contingent gating model. Upon evaluating heterotypic Cx37/Cx45 GJs, it was revealed that the channels can be modulated by few millivolt differences in the membrane potentials; complementing the observations in another study (Emerson and Segal, 2000). Preliminary single channel analysis of Cx37/Cx43 revealed that the voltage dependent i_j rectifications were continuously observed at the single channel level and the presence of the different V_j -gating mechanisms. However more experiments will be needed for proper statistical analysis. Finally designed docking variants in Cx40 E1 or E2 domains (D55N or P193Q respectively) successfully rescued the coupling status and G_j for heterotypic Cx37/Cx40 GJs. Data from the present study with previous investigations on human vascular connexins suggest that human Cx40 may not belong in the same group of docking compatible connexins as Cx37, Cx43 and Cx45.

Curriculum Vitae

Name: Nicholas Kiwon Kim

Post-secondary Education and Degrees: University of Western Ontario
London, Ontario, Canada
2012-2016 BMSc

University of Western Ontario
London, Ontario, Canada
2016-2018 MSc (Expected October 2018)

Honors and Awards: Entrance Scholarship (\$2000)
University of Western Ontario

Dean's Honor List
2013-2016

Related Work Experience: Teaching Assistant
University of Western Ontario
2016-2018

Publications:

Ye WG, Yue B, Aoyama H, Kim NK, Cameron JA, Chen HH, Bai D. (2017). Human Cx40 does not form functional heterotypic gap junction channels with Cx45. JMCC, (111), 17-26.

Tejada MG, Sudhakar S, Kim NK, Aoyama H, Shilton BH, Bai D. (Under revision). Putative pore lining residues and [Mg²⁺]_i influence Cx50 unitary gap junction channel conductance. BJ, (n/a),

Presentations: London Health Research Day Poster Presentation
March 2017

Physiology Pharmacology Research Day Poster Presentation
November 2017

Nexin (Connexin & Pannexin) Forum
April 2018

London Health Research Day Poster Presentation
May 2018
