THE SINGULARITY OF THE INFORMATION MATRIX OF THE MIXED PROPORTIONAL HAZARD MODEL*

BY GEERT RIDDER AND TIEMEN WOUTERSEN†
University of Southern California and University of Western Ontario
July 30, 2002

KEYWORDS: Duration, Semi-parametric Efficiency Bound, Mixed Proportional Hazard.

1 Introduction

We reconsider the efficiency bound for the semi-parametric Mixed Proportional Hazard (MPH) model with parametric baseline hazard and regression function. This bound was first derived by Hahn (1994). One of his results is that if the baseline hazard is Weibull, the information matrix is singular, even if the model is semi-parametrically identified†. This implies that neither the Weibull parameter nor the regression coefficients can be estimated at a $N^{-1/2}$ rate (Ishwaran (1996a) and Van der Vaart (1998, Theorem 25.32)).

Hahn's result had an impact on the use of MPH models in empirical research. The singularity of the information matrix seems to confirm the results of simulation studies, see e.g. Baker and Melino (2000), that suggest that it is difficult to estimate both the baseline hazard and the distribution of the random effects (or unobserved heterogeneity) with a sufficient degree of accuracy with the sample sizes that one encounters in practice.

Indeed Honoré's (1990) estimator for the parameters of a semi-parametric Weibull MPH

model converges at a rate slower than but arbitrarily close to \(N^{-1/3}\). Ishwaran (1996b) shows that the Weibull parameter can be estimated at a rate of at most \(N^{-2/d+1}\) if the moments of the unobserved heterogeneity up to \(d+1\) are bounded. Altogether these results seem to imply that although the MPH model is semi- and even non-parametrically identified, the estimation of the parameters of a semi-parametric MPH model requires a larger dataset than usual.

In this note we show that this impression is false. In particular, we show that the information matrix is singular if and only if the parametric model of the (integrated) baseline hazard is closed under the power transformation. A set of integrated baseline hazards \(\mathcal{H}\) is closed under the power transformation if \(h(t) \in \mathcal{H}\) implies \(h(t)^\alpha \in \mathcal{H}\) for every \(\alpha > 0\). The Weibull baseline hazard is the most prominent member of this class of models. All models that are closed under the power transformation have a baseline hazard that is either 0 or \(\infty\) for \(t = 0\), so that the restriction that the baseline hazard at 0 is bounded away from 0 and \(\infty\) rules out closedness under the power transformation. Under this restriction the information matrix is nonsingular.

We also show that the MPH model is semi-parametrically identified if we restrict the baseline hazard near 0 to be bounded away from 0 and \(\infty\). Hence, there are (at least) two restrictions that are sufficient for semi-parametric identification: (i) the restriction that the mean of the unobserved multiplicative random effect is finite (Elbers and Ridder (1982)^3), and (ii) the restriction that the baseline hazard near 0 is bounded away from 0 and infinity. The first restriction does not preclude that the information matrix is singular, the second restriction does. Hence, if we impose the second restriction there may exist estimators that are \(N^{-1/2}\) consistent. Under the first restriction the upper bound of the rate of convergence is \(N^{-\frac{1}{3}}\) (Ishwaran (1996a)).

Is there empirical and theoretical support for the assumption that the baseline hazard is bounded from 0 and \(\infty\) near \(t = 0\)? First, it should be noted that boundedness of the hazard of the duration given the covariates, i.e. ignoring unobserved heterogeneity, from 0 and \(\infty\) near \(t = 0\), implies the same property of the baseline hazard in the MPH model. This makes
the assumption on the baseline hazard testable (the boundedness from $\infty$ by testing whether one over the hazard is significantly different from 0). Second, the MPH model has been used frequently in empirical studies. Strictly, the assumption that the baseline hazard is bounded from 0 and $\infty$ is not testable without further assumptions, because the MPH model may not be identified if this assumption does not hold. However, if the baseline hazard is specified such that its value near $t = 0$ is estimated without restrictions, e.g. by using a piecewise constant hazard, one can construct a confidence interval for that value (and its inverse). Meyer (1990), (1996) estimates such an MPH model for unemployment durations and his estimates show that the baseline hazard is bounded from 0 and $\infty$ near $t = 0$. The same conclusion can be drawn from Kennan’s (1985) study of strike durations. He does not use an MPH, but a discrete hazard model, but the daily settlement hazards are clearly positive from the start and, although the hazard is decreasing/increasing, the hazard near $t = 0$ is not exceptionally large. From a search of the empirical literature we conclude that there is prima facie evidence that the assumption that the baseline hazard is bounded from 0 and $\infty$ near $t = 0$ holds in most, but not all, studies. Third, if we think of the MPH model as a reduced form approximation of a hazard model that is derived from economic theory, then it is important to check whether theoretical models have hazards that are bounded from 0 and $\infty$ near $t = 0$. We can refer to Van den Berg’s (1990) study of non-stationary job search. In his model the reservation wage path is bounded and this implies that if the arrival rate of job offers is bounded from 0 and $\infty$ near $t = 0$, then the re-employment hazard also has that property. Blau and Robins (1986) estimate the offer arrival rate and from their estimates we conclude that it satisfies the assumption. Yoon (1985) derives a closed form solution of the non-stationary job search model that is bounded from 0 and $\infty$ near $t = 0$.

The MPH model can be expressed as a transformation model with a scale normalization. Horowitz (1996) derives a semi-parametric estimator for transformation models, and Horowitz (1999) proposes an estimator of the scale parameter that, if the first three moments of the multiplicative unobserved heterogeneity are bounded, converges at a rate that is arbitrarily close to $N^{-\frac{2}{3}}$. We develop an estimator for the scale parameter under the as-
assumption that the baseline hazard near $t = 0$ is constant and bounded from 0 and $\infty$, but no parametric assumptions are imposed on the baseline hazard for other values of $t$. This estimator converges at rate $N^{-1/2}$. Combining this estimator of the scale parameter with Horowitz' (1996) estimators of the other parameters in the MPH model yields estimators for the integrated baseline hazard and the regression coefficients that converge at rate $N^{-\frac{1}{2}}$.

This paper is organized as follows. In section 2 we discuss the semi-parametric MPH model and its efficiency bound as obtained by Hahn (1994). We also give an example that shows that if we change the Weibull baseline hazard slightly so that it is bounded away from 0 and $\infty$ at 0, then the information matrix becomes nonsingular. Section 3 contains the main result. Section 4 discusses the implications for estimation and section 5 concludes.

2 The Semi-parametric MPH Model: Identification and Efficiency Bound

2.1 The semi-parametric MPH model

We consider the semi-parametric MPH model for the conditional distribution of $T$ given a vector of non-constant covariates $X$

\begin{equation}
\theta(t \mid X, U; \alpha, \beta) = \lambda(t, \alpha)e^{\beta'X}e^U
\end{equation}

with parametric baseline hazard $\lambda(t, \alpha)$, regression function $e^{\beta'X}$, and $(\alpha, \beta)$ in a parameter space that is an open subset of the Euclidean space of conforming dimension. The unobserved covariates are captured by the random effect $U$. For example, for the Weibull model we have $\theta(t \mid X, U; \alpha, \beta) = at^{\alpha-1}e^{\beta'X}e^U$ where $\alpha > 0$. The unconditional (on $U$) integrated hazard at the population values of the parameters is defined as

\begin{equation}
S = \Lambda(T, \alpha_0)e^{\beta_0'X}
\end{equation}

with $\Lambda(t, \alpha) = \int_0^t \lambda(s, \alpha)ds$. In appendix 1, we show that

\begin{equation}
S \overset{d}{=} \frac{W}{e^U}
\end{equation}

with $W$ a standard exponential random variable that is independent of $U, X$ and $\overset{d}{=}$ means that the random variables on both sides have the same distribution.
2.2 Semi-parametric identification

Elbers and Ridder (1982) show that this MPH model is semi-parametrically identified if the following assumptions hold.

(A1) \( \Lambda(t_0, \alpha_0) = 1 \) for some \( t_0 > 0 \), and \( \Lambda(\infty, \alpha_0) = \infty \).

(A2) \( E(e^U) < \infty \).

(A3) There are \( x_1, x_2 \) in the support of \( X \) with \( \beta'_0 x_1 \neq \beta'_0 x_2 \) and there is no constant in \( X; U \) and \( X \) are independent.

(A4) If \( \lambda(t, \alpha_0) = \lambda(t, \tilde{\alpha}_0) \) for all \( t > 0 \), then \( \alpha_0 = \tilde{\alpha}_0 \), and if \( \beta'_0 x = \tilde{\beta}'_0 x \) for all \( x \) in the support of \( X \), then \( \beta_0 = \tilde{\beta}_0 \).

The first part of assumption A1 and the absence of a constant in \( X \) are normalizations. Assumption A4 ensures parametric identification of \( \alpha_0, \beta_0 \).

We propose an alternative for assumption A2.

(A2*) \( 0 < \lim_{t \to 0} \lambda(t, \alpha_0) = \lambda(0, \alpha_0) < \infty \).

Ishwaran (1996a) shows that there exist a nonnegative random variable \( U_1 \) and a \( \sigma > 0 \) such that \( \frac{\sigma}{\sigma^*} \leq \frac{\sigma}{\sigma^*} \). If we omit covariates, the observationally equivalent MPH model has integrated baseline hazard \( \Lambda(t, \alpha_0)^{\frac{1}{\sigma}} \) which does not satisfy A2*. Hence A2* precludes Ishwaran's construction of an observationally equivalent MPH model. Assumptions A1, A2*, A3-A4, are sufficient for the semi-parametric identification of the MPH model.

Proposition 1

If the conditional distribution of \( T \) given \( X \) has a distribution with a (conditional) hazard as in (1) and if assumptions A1, A2*, A3, and A4 are satisfied, then \( \alpha_0, \beta_0 \) and the distribution of \( U \) are identified, i.e. there are no observationally equivalent \( \tilde{\alpha}_0, \tilde{\beta}_0 \).

Proof: See appendix 2.

Although both sets of conditions ensure that the semi-parametric MPH model is identified, they have different implications for the information bound of this model. In particular,
with the finite mean assumption the information matrix can be singular, while with assumption A2* this cannot be the case.

Examples of parametric models where assumption A2* holds for all parameter values are the Gompertz baseline hazard, the rational log specification (Lancaster (1990)), and the normal hazard. See Klein and Moeschberger (1997) for a discussion of these specifications. Examples of models in which assumption A2* is a parametric restriction are the piecewise-constant baseline hazard and the Box-Cox baseline hazard of Flinn and Heckman (1982)\(^5\). Finally, the lognormal hazard does not satisfy A2* for all parameter values.

### 2.3 The information bound of the MPH model

Hahn (1994, p. 610) derives the efficient score of the MPH model using the following assumptions.

(B1) \(\lambda(t, \alpha)\) and \(\Lambda(t, \alpha)\) are continuously differentiable with respect to \(\alpha\) on an open set that contains \(\alpha_0\).

(B2) \(E(X'X) < \infty\) and there exist non-negative functions \(\zeta_i(T, X)\), \(i = 1, 2, 3\) such that

\[
\frac{\partial \ln \lambda(T, \alpha)}{\partial \alpha} \leq \zeta_1(T)
\]

\[
e^{g'X} \frac{\partial \Lambda(T, \alpha)}{\partial \alpha} \leq \zeta_2(T, X)
\]

\[
X e^{g'X} \Lambda(T, \alpha) \leq \zeta_3(T, X)
\]

with \(E(\zeta_1(T)^2) < \infty\), \(E(e^{2U} \zeta_i(T, X)^2) < \infty\), \(i = 2, 3\).

The variance matrix of the efficient score at the population parameters \(\alpha_0, \beta_0\) is the information matrix. The efficient score is

(4) \[ l = \begin{bmatrix} l_\alpha \\ l_\beta \end{bmatrix} = \begin{bmatrix} a_{11} - a_{12} S \cdot E[e^U | S] \\ a_{21} - a_{22} S \cdot E[e^U | S] \end{bmatrix}. \]
with

\[
\begin{align*}
  a_{11} &= \frac{\partial \ln \lambda(T, \alpha)}{\partial \alpha} - E \left[ \frac{\partial \ln \lambda(T, \alpha)}{\partial \alpha} | S \right] \\
  a_{12} &= \frac{\partial \ln \Lambda(T, \alpha)}{\partial \alpha} - E \left[ \frac{\partial \ln \Lambda(T, \alpha)}{\partial \alpha} | S \right] \\
  a_2 &= X - E(X|S) = X - E(X),
\end{align*}
\]

(5)

see Hahn (1994, Theorem 1)\(^6\). Without loss of generality we assume that \(E(X) = 0\).

For the Weibull baseline hazard \(\lambda(t, \alpha) = \alpha t^{\alpha-1}\) we have

\[
a_{11} = a_{12} = \ln T - E(\ln T|S)
\]

(6)

and by (2) \(\ln T = \frac{\ln S - \beta_0 X}{\alpha_0}\) so that

\[
a_{11} = a_{12} = -\frac{\beta_0'}{\alpha_0} X.
\]

(7)

Substitution in (4) yields

\[
l = (1 - SE(\varepsilon^U|S)) \left[ -\frac{\beta_0 X}{\alpha_0} \right]
\]

(8)

so that the distribution of the efficient score is singular at the population parameter values as is its variance matrix. This is the argument given by Hahn (1994, p. 614).

Note that this argument is not restricted to the Weibull baseline hazard. It applies to all integrated baseline hazards of the form \(\lambda(t, \gamma, \alpha) = h(t, \gamma)^\alpha\) with \(h\) a strictly increasing function of \(t\) with \(h(0, \gamma) = 0\). However, a small modification of the Weibull baseline hazard gives a nonsingular information matrix. Consider the translated Weibull with integrated baseline hazard \(\Lambda_x(t, \alpha) = (t + \varepsilon)^\alpha - \varepsilon^\alpha\) with \(\varepsilon > 0\) a known constant. Note that this class of integrated baseline hazard models is not closed under the power transformation. Also the baseline hazard of this model is bounded away from 0 and \(\infty\) if \(\varepsilon > 0\). A direct calculation shows that the information matrix is nonsingular.

3 Necessary and Sufficient Conditions for the Singularity of the Information Matrix

Our main result is
Proposition 2

Under assumptions A1, A3-A4, and B1-B2 the information matrix is singular if and only if the integrated baseline hazard is of the form \( \Lambda(t, \alpha) = h(t)^{d(\alpha)} \) for \( \alpha \) in some open neighborhood of \( \alpha_0 \) with \( h \) a strictly increasing continuous function with \( h(0) = 0 \), \( h(\infty) = \infty \) and with \( d(\alpha) > 0 \).

Proof: See appendix 3.

The proof of Proposition 2 can be extended to the case of two or more parameters\(^7\). The baseline hazard that corresponds to \( \Lambda(t, \alpha) = h(t)^{d(\alpha)} \) is

\[
\lambda(t, \alpha_0) = d(\alpha_0) h(t)^{d(\alpha_0) - 1} h'(t).
\]

Note that the proposition only restricts \( d(\alpha_0) \) to be positive. In particular, it can be either smaller or larger than 1. If \( d(\alpha_0) < 1 \), then by (9) \( \lim_{t \to 0} \lambda(t, \alpha_0) = \infty \). If \( d(\alpha_0) > 1 \), then \( \lim_{t \to 0} \lambda(t, \alpha_0) = 0 \). Only if \( d(\alpha_0) = 1 \), the baseline hazard at 0 can be bounded away from 0 and \( \infty \). Hence we have

Theorem

If the assumptions for Proposition 2 hold, then \( 0 < \lim_{t \to 0} \lambda(t, \alpha_0) < \infty \) implies that the information matrix of the semi-parametric MPH model in (1) is nonsingular.

4 Implications for Estimation

A consequence of the theorem is that if we impose \( A2^* \) there may exist estimators of the regression coefficients and the parameters of the integrated baseline hazard that converge at a rate \( N^{-\frac{1}{2}} \). In this section we discuss some estimators for semi-parametric MPH models that satisfy \( A2^* \). We also develop an estimator for the case that the baseline hazard is constant near 0, but non-parametric for other values of \( t \). In both cases the parameters are estimated at rate \( N^{-\frac{1}{2}} \).

If the baseline hazard is specified for all \( t \geq 0 \), estimation starts from the observation that if we define \( \Lambda(T, \alpha) \exp(\beta' X) = S(X, \alpha, \beta) \), then under weak conditions the distribution of \( S \) is independent of \( X \) if and only if \( \alpha = \alpha_0, \beta = \beta_0 \). Estimators as the Quantile Censoring estimator (Ridder and Woutersen (2002)) and the Linear Rank estimator (Bijwaard
and Ridder (2002)) use this observation to formulate (potentially a continuum of) moment conditions. A proof that their moment conditions identify the parameters of the semiparametric MPH model, even if the durations are censored, is beyond the scope of the present paper. Note that these moment conditions cannot identify the parameter \( \sigma \) of a power transformation of \( \Lambda(t, \alpha) \) and corresponding scale of \( \beta \). However, by assumption A2* there are no observationally equivalent models with \( \sigma \neq 1 \).

Next consider the case that the baseline hazard is only specified near 0. Taking the logarithm of (2) gives, by appendix 1

\[
\ln \Lambda(T, \alpha) = -\beta' X - U + \ln W.
\]

This is essentially a transformation model with transformation \( H = \ln \Lambda \) and random error \(-U + \ln W\). Horowitz (1996) suggests using existing single index estimators for \( \beta \) and he proposes a nonparametric estimator for \( H \). This estimator (and the single index estimator) estimate \( \ln(\Lambda(t)) \) (and \( \beta \)) up to a multiplicative scale parameter \( \sigma \). In the MPH model this scale parameter is identified either by an assumption on the moments of \( e^U \) or by assumption A2*. Horowitz (1999) proposes an estimator for the scale parameter that converges at rate arbitrarily close to \( N^{-\frac{3}{4}} \). Now assume, as in Meyer (1990), that the baseline hazard is constant over a small interval near 0, i.e. \( 0 < \lambda(t) = \lambda(0) < \infty \) for \( 0 \leq t \leq 2 \epsilon \). Moreover, suppose that assumptions 1-9 of Horowitz (1996) hold and that we can estimate the transformation (up to scale) over the interval \( [\epsilon, \tau] \) where \( \tau > 2 \epsilon \). Denote the estimator of the transformation by \( \hat{H}(\hat{t}) \). This estimator converges at rate \( N^{-\frac{1}{2}} \) (Horowitz (1996, theorem 1)). Because \( H(t) = \sigma \ln \Lambda(t) \) we have \( H(2 \epsilon) - H(\epsilon) = \sigma \ln 2 \), so that we estimate the scale parameter \( \sigma \) by

\[
\hat{\sigma}_N = \frac{\hat{H}(2 \epsilon) - \hat{H}(\epsilon)}{\ln 2}.
\]

The integrated baseline hazard and the regression parameters can be estimated using \( \hat{\sigma}_N \). All these estimators converge at rate \( N^{-\frac{1}{2}} \).
5 Conclusion

The condition that the baseline hazard is bounded away from 0 and \( \infty \) near \( t = 0 \) is sufficient for semi-parametric identification. This condition is also sufficient for a nonsingular information matrix. Hence, if the parametric baseline hazard is bounded from 0 and \( \infty \) near \( t = 0 \), there may exist (regular) estimators of the parameters of the semi-parametric MPH model with a parametric baseline hazard and regression function that are \( N^{-1/2} \) consistent. In particular, we develop an estimator for the scale parameter in the MPH model (and hence the integrated baseline hazard and the regression parameters) under the assumption that the baseline hazard is constant and bounded from 0 and \( \infty \) in a small interval near zero. This estimator converges at rate \( N^{-1/2} \).

The restriction \( 0 < \lim_{t \to 0} \lambda(t, \alpha_0) = \lambda(0, \alpha_0) < \infty \), is an alternative for restrictions that bound the moments of the multiplicative unobserved heterogeneity. Both are sufficient for semi-parametric identification. However, under the restriction on the baseline hazard, the information matrix of the semi-parametric MPH model is nonsingular, so that \( N^{-1/2} \) consistent estimators may (and indeed do) exist.

The restriction on the baseline hazard is testable. A sufficient (but not necessary) condition for the boundedness of the baseline hazard from 0 and \( \infty \) near \( t = 0 \) is that the conditional hazard given the covariates (but not the unobserved heterogeneity) and the inverse of this conditional hazard are significantly different from 0 near \( t = 0 \).

6 Appendices

Appendix 1 Distribution of \( S = \Lambda(T, \alpha_0) e^{\beta_0 X} \).

We have \( \Pr(T > t | X, U) = \exp \left( -\Lambda(t, \alpha_0) e^{\beta_0 X} e^U \right) \). Hence \( \Pr \left( \Lambda(T, \alpha_0) e^{\beta_0 X} > s | X, U \right) = \Pr \left( T > \Lambda^{-1} \left( se^{-\beta_0 X} \alpha_0 \right) | X, U \right) = e^{-se^U} \). Because \( U \) and \( X \) are independent we have \( \Pr(S > s | X) = E(e^{-se^U}) \) and \( \Pr(S > s) = E(e^{-se^U}) \).

Appendix 2 Proof of Proposition 1
By (2) and (3) we have for all $t > 0$

$$Pr(T \leq t | X) = F_V \left( \Lambda(t, \alpha_0) e^{\beta_0 X} \right)$$

where $V = \frac{W}{c^t}$ is distributed as a mixture of exponential distributions and hence has a strictly increasing cdf $F_V$. We can assume that $\Lambda(t, \alpha_0)$ is strictly increasing in $t$ without loss of generality. If $\tilde{\alpha}_0, \tilde{\beta}_0, \tilde{U}$ are observationally equivalent, then for all $t > 0$

$$F_V \left( \Lambda(t, \alpha_0) e^{\beta_0 X} \right) = F_{\tilde{V}} \left( \Lambda(t, \tilde{\alpha}_0) e^{\tilde{\beta}_0 X} \right). \tag{13}$$

We denote $\Lambda(t, \alpha_0) = \Lambda(t), \Lambda(t, \tilde{\alpha}_0) = \tilde{\Lambda}(t), e^{-\beta_0 x_1} = \phi_1, e^{-\beta_0 x_2} = \phi_2, e^{-\tilde{\beta}_0 x_1} = \tilde{\phi}_1, e^{-\tilde{\beta}_0 x_2} = \tilde{\phi}_2$ with $x_1, x_2$ as in A3 and without loss of generality $1 = \phi_1 > \phi_2, 1 = \tilde{\phi}_1 > \tilde{\phi}_2$.

The inverse of a strictly increasing function exits and from (13) for all $t > 0$

$$F_{\tilde{V}} \left( \tilde{\Lambda}^{-1}(\tilde{t}\tilde{\phi}_2) \right) = F_{\tilde{V}}(t) = F_V \left( \Lambda^{-1}(t) \right). \tag{14}$$

If we denote $K = \Lambda \left( \tilde{\Lambda}^{-1}(t) \right)$ with $K$ strictly increasing and $K(0) = 0$, then (14) implies that

$$K(t\tilde{\phi}_2) = \phi_2 K(t) \tag{15}$$

and by iteration for all $n \geq 1$

$$K(t\tilde{\phi}_2^n) = \phi_2^n K(t). \tag{16}$$

If we take the derivative of (15) we obtain

$$\frac{\phi_2}{\tilde{\phi}_2} K'(t) = K'(t\tilde{\phi}_2) \tag{17}$$

and by iteration for all $n \geq 1$

$$\left( \frac{\phi_2}{\tilde{\phi}_2} \right)^n K'(t) = K'(t\tilde{\phi}_2^n) \tag{18}.$$ 

Taking the ratio of (18) and (16) we obtain because $K'(t) = \frac{\lambda(\Lambda^{-1}(t))}{\lambda(\Lambda^{-1}(0))}$ with $\lambda(t) = \lambda(t, \alpha_0)$.

$$\tilde{\lambda}(t) = \lambda(t, \tilde{\alpha}_0)$$

$$\frac{K'(t)}{K(t)} = \lim_{t \to \infty} \frac{K'(t\tilde{\phi}_2^n)}{K(t\tilde{\phi}_2^n)} = \lim_{n \to \infty} \frac{1}{t} \frac{\lambda(\tilde{\Lambda}^{-1}(t\tilde{\phi}_2^n))}{\tilde{\lambda}(\tilde{\Lambda}^{-1}(t\tilde{\phi}_2^n))} = \frac{1}{t} \frac{\lambda(\Lambda^{-1}(t\tilde{\phi}_2^n))}{\phi_1^n} \tag{19}.$$
by assumption A1. Because \( K(0) = 0 \) this implies that \( K(t) = t \) and hence \( \lambda(t, \alpha_0) = \lambda(t, \tilde{\alpha}_0) \)
for \( t > 0 \) so that \( \alpha_0 = \tilde{\alpha}_0 \) by A4. By (15) \( \beta'_0 x_2 = \tilde{\beta}_0, x_2 \) for all \( x_2 \) in the support of \( X \) and hence \( \beta_0 = \tilde{\beta}_0 \) by A4.

**Appendix 3 Proof of Proposition 2**

We first rewrite the efficient score in (4) and (5) to reflect the dependence on \( T, X, S \) and the parameters,

\[
 l = \begin{bmatrix} l_\alpha \\ l_\beta \end{bmatrix} = \begin{bmatrix} a_{11}(T, S, \alpha_0) - a_{12}(T, S, \alpha_0) H_U(S) \\ X(1 - H_U(S)) \end{bmatrix}
\]

with \( Z = \beta'_0 X \) and \( H_U(S) = SE(e^U|S) \). Note that by (3) \( H_U \) does not depend on the parameters. Because \( S \) and \( Z \) are independent we have

\[
 a_{11}(T, S, \alpha_0) = \frac{\partial \ln \Lambda(T, \alpha)}{\partial \alpha}|_{\alpha = \alpha_0} - E_Z \left[ \frac{\partial \{ \ln \Lambda^{-1}(Se^{-Z}, \alpha_0) \}}{\partial \alpha}|_{\alpha = \alpha_0} \right]
\]

\[
 a_{12}(T, S, \alpha_0) = \frac{\partial \ln \Lambda(T, \alpha)}{\partial \alpha}|_{\alpha = \alpha_0} - E_Z \left[ \frac{\partial \{ \ln \Lambda^{-1}(Se^{-Z}, \alpha_0) \}}{\partial \alpha}|_{\alpha = \alpha_0} \right].
\]

where by (2) the variables \( T, S, Z \) are related by

\[
 \ln \Lambda(T, \alpha_0) + Z = \ln S.
\]

By assumptions B1 and B2 the information bound is continuous in \( \alpha_0 \). We first consider the case that \( \alpha_0 \) is a scalar. If the information matrix has a rank equal to the number of regressors in \( X \), i.e. one less than full rank, for some value \( \alpha_0 \), then by continuity it has the same rank for population parameters in a small neighborhood of \( \alpha_0, B(\alpha_0) \). Note that \( T \) depends on \( X \) only through \( \beta'_0 X \). By assumption A4 the linear combination that makes the score singular must contain \( l_\alpha \). Because \( l_\alpha \) depends on \( X \) only through \( \beta'_0 X \), loss of rank occurs if and only if \( l_\alpha \) is proportional to \( \beta'_0 X \), i.e. there is a \( c(\alpha) \neq 0 \) on \( B(\alpha_0) \) such that

\[
 c(\alpha) a_{11}(T, S, \alpha) - c(\alpha) a_{12}(T, S, \alpha) H_U(S) = Z(1 - H_U(S))
\]

for \( \alpha \) in \( B(\alpha_0) \), and \( S \geq 0, Z, T \) that satisfy (21). From (22) it follows that for \( \alpha \in B(\alpha_0) \)

\[
 a_{11}(t, s, \alpha) = a_{12}(t, s, \alpha)
\]

12
for if this equality does not hold for some $\alpha \in B(\alpha_0)$, it does not hold on some open interval, because of B1 and B2. Moreover, there is a $t$ such that $a_{11}(t, s, \alpha), a_{12}(t, s, \alpha)$ are not constant in $\alpha$ on that interval by assumption A4. Hence only if the equality holds we can find a function $c(\alpha)$ such that the left-hand side does not depend on $\alpha$.

Substitution in (23) gives that for all $\alpha \in B(\alpha_0)$ and $s \geq 0$ and $t$ that satisfy (21) for some $z$ in the support of $Z$

\[
\frac{\partial \ln \lambda(t, \alpha)}{\partial \alpha} - E_Z \left[ \frac{\partial \ln \lambda(\Lambda^{-1}(se^{-Z}, \alpha), \alpha)}{\partial \alpha} \right] - \frac{\partial \ln \Lambda(t, \alpha)}{\partial \alpha} - E_Z \left[ \frac{\partial \ln \Lambda(\Lambda^{-1}(se^{-Z}, \alpha), \alpha)}{\partial \alpha} \right] = 0.
\]

Note that both $a_{11}$ and $a_{12}$ are identically equal to 0 if $Z$ takes only one value. If $Z$ takes two (or more) values, then (24) holds if and only if for $\alpha \in B(\alpha_0)$ and $t > 0$

\[
\frac{\partial \ln \lambda(t, \alpha)}{\partial \alpha} - \frac{\partial \ln \Lambda(t, \alpha)}{\partial \alpha} = f(\alpha).
\]

Integrating first with respect to $\alpha$ and next with respect to $t$ gives (using the initial value $\Lambda(t_0, \alpha) = 1$)

\[
\ln \Lambda(t, \alpha) = e^{\int_{t_0}^{t} k(s)ds} \int_{t_0}^{t} e^{k(s)}ds
\]

for $\alpha \in B(\alpha_0)$ and with $k(t)$ the integration constant for the integration with respect to $\alpha$. Also $\int_{t_0}^{0} k(s)ds = -\infty$ and $\int_{t_0}^{\infty} k(s)ds = \infty$. If we define $h(t) = \exp(\int_{t_0}^{t} k(s)ds)$ and $d(\alpha) = \exp(\int_{t_0}^{\infty} f(\gamma)d\gamma)$, we find for $\alpha \in B(\alpha_0)$

\[
\Lambda(t, \alpha) = h(t)^{d(\alpha)}
\]

with $h$ an increasing function with $h(0) = 0$ and $h(\infty) = \infty$. This completes the proof.

Notes

1 The singularity holds if we have single-spell duration data. Hahn shows that the efficiency bound is nonsingular, if we have two or more spells for the same individual provided that the individual random effect is the same for both spells.

2 That is by a regular estimator sequence (for a definition see Van der Vaart (1998), p. 115).

3 See also Jewell (1982) and Heckman and Singer (1984) who consider an alternative identifying assumption that allows for an infinite mean, but assumes that the power transformation is fixed.

4 References can be found on our webpages www.rcf.usc.edu/~ridder/ and www.ssc.uwo.ca/economics/faculty/Woutersen.

5 The logarithm of this hazard model has the following form, \( \ln(\lambda(t, \alpha)) = \gamma_1 \frac{t^{\gamma_1-1}}{\lambda_1} + \gamma_2 \frac{\alpha^{\gamma_2-1}}{\lambda_2} \) where \( \lambda_2 > \lambda_1 \geq 0 \); condition A2* holds if and only if \( \lambda_1 > 0 \). With this restriction the baseline hazard still can be non-monotonic, e.g. ‘bathtub’ shaped.

6 The efficient score is well-defined even if \( E(V) = \infty \); the proof is available at our webpages.

7 The proof is available at our webpages.
Omitted appendices of The Singularity of the Information Matrix of the Mixed Proportional Hazard Model

Appendix A Existence of the score if $E(V) = \infty$.

We have

$$E(e^U | S) = \frac{E(e^{2U} e^{-Se^U})}{E(e^{U} e^{-Se^U})}$$

Because $\frac{x^2 e^{-zx}}{\alpha^2} \leq 4\alpha e^{-2}$ the numerator is bounded by $\frac{4\alpha}{\beta^2} e^{-2}$. Because the distribution of $e^U$ is not degenerate in 0, there are $0 < v_1 < v_2$ with $Pr(v_1 < e^U \leq v_2) > 0$. Hence the denominator is greater than $\min\{v_1 e^{-Sv_1}, v_2 e^{-Sv_2}\} \Pr(v_1 < e^U \leq v_2) > 0$. Hence

$$E(e^U | S) \leq \frac{\frac{4\alpha}{\beta^2} e^{-2}}{\min\{v_1 e^{-Sv_1}, v_2 e^{-Sv_2}\} \Pr(v_1 < e^U \leq v_2)}$$

Appendix B The information matrix for translated Weibull baseline hazard.

The score is evaluated at $\alpha = \alpha_0$ so that

$$a_{11} = \frac{1}{\alpha_0} \ln \left( e^{-\beta_0 X S + \epsilon^\alpha} \right) - \frac{1}{\alpha_0} E_X \left[ \ln \left( e^{-\beta_0 X S + \epsilon^\alpha} \right) \right]$$

$$a_{12} = \frac{\beta_0 X}{\alpha_0 S} \left( e^{-\beta_0 X S + \epsilon^\alpha} \right) \ln \left( e^{-\beta_0 X S + \epsilon^\alpha} \right) - E_X \left[ \frac{\beta_0 X}{\alpha_0 S} \ln \left( e^{-\beta_0 X S + \epsilon^\alpha} \right) \ln \left( e^{-\beta_0 X S + \epsilon^\alpha} \right) \right] -$$

$$- \frac{e^{-\beta_0 X S + \epsilon^\alpha} \ln \epsilon}{S} + E_X \left[ \frac{e^{-\beta_0 X S + \epsilon^\alpha} \ln \epsilon}{S} \right].$$

To see that the distribution of the efficient score is nonsingular, consider the special case $U = 0$ so that $E[e^U | S] = 1$. Then a necessary condition for singularity is that

$$a_{11} - a_{12}S = \frac{1}{\alpha_0} \ln \left( e^{-\beta_0 X S + \epsilon^\alpha} \right) - \frac{1}{\alpha_0} E_X \left[ \ln \left( e^{-\beta_0 X S + \epsilon^\alpha} \right) \right] -$$

$$- \frac{\beta_0 X}{\alpha_0} \left( e^{-\beta_0 X S + \epsilon^\alpha} \right) \ln \left( e^{-\beta_0 X S + \epsilon^\alpha} \right) +$$
\[ + E_X \left[ \frac{e^{\beta X}}{e^{\alpha_0}} \left( e^{-\beta_1 X} S + e^{\alpha_0} \right) \ln \left( e^{-\beta_1 X} S + e^{\alpha_0} \right) \right] + \\
+ \frac{e^{\beta X} e^{\alpha_0} \ln \varepsilon}{S} - E_X \left[ \frac{e^{\beta X} e^{\alpha_0} \ln \varepsilon}{S} \right] \]

is constant in \( S \) for all \( x \) in the support of \( X \), and this is true if and only if \( \varepsilon = 0 \).

**Appendix C** Proof of Proposition 2 if the number of parameters in the baseline hazard is greater than 1.

If \( \alpha \) is a vector and \( \alpha \in B(\alpha_0) \), (25) becomes

\[ c(\alpha) \frac{\partial \ln \lambda(t, \alpha)}{\partial \alpha} - c(\alpha) \frac{\partial \ln \Lambda(t, \alpha)}{\partial \alpha} = f(\alpha) \]

for some vector \( c(\alpha) \) and a function, \( f(\alpha) \). Consider the case that \( \alpha \) has two parameters.

Then from (30)

\[ \frac{\partial \ln \lambda(t, \alpha)}{\partial \alpha_1} - \frac{\partial \ln \Lambda(t, \alpha)}{\partial \alpha_1} = \frac{f(\alpha)}{c_1(\alpha)} - \frac{c_2(\alpha)}{c_1(\alpha)} \left( \frac{\partial \ln \lambda(t, \alpha)}{\partial \alpha_2} - \frac{\partial \ln \Lambda(t, \alpha)}{\partial \alpha_2} \right). \]

Integrating with respect to \( \alpha_1 \) and \( t \) yields the representation \( \Lambda(t, \alpha) = h(t, \alpha) d(\alpha) \) with

\[ d(\alpha) = e^{\int_{\alpha_0}^{\alpha_1} f(\gamma, \alpha_2) d\gamma} \quad \text{and} \quad \ln h(t, \alpha_0) = \int_{t_0}^{t} e^{-k(\gamma, \alpha_2)} \int_{\alpha_0}^{\alpha_1} c_1(\gamma, \alpha_2) \left( \frac{\partial \ln \lambda(t, \gamma, \alpha_2)}{\partial \alpha_2} \right) d\gamma \, ds \]

so that Proposition 2 still holds with an obvious modification.

**Appendix D**

**Addendum:** Duration dependence near 0 in empirical research

**Structural/empirical papers not MPH**

In some papers only a graph of the baseline hazard is provided, and no estimates (with standard errors).

1. Van den Berg, ReStud (1990). Unemployment durations. Hazard is \( \theta(t, \alpha) = \lambda \overline{F}(\phi(t)) \) with \( \phi(t) \) the time-varying reservation wage. In his application \( \phi(t) \) is bounded and the arrival rate and wage offer distribution are time constant. Hence the hazard near 0 is bounded from 0 and \( \infty \).
2. Blau and Robins, J. of Public Economics (1986). Unemployment durations (days). Piecewise constant baseline hazard (exponential specification) no unobserved heterogeneity. Estimates of offer arrival rate (Tables 2-3) and re-employment hazard (Table 4). Baseline hazard in first 10 weeks not different.

Reduced form studies (not Weibull)

1. Arulampalam and Stewart, Econ Journal (1995). Unemployment durations. Meyer type grouped duration model with piecewise constant baseline hazard (weeks), no unobserved heterogeneity. Baseline hazard is in Figure 1, p.327. Greater than 0 and finite near 0.

2. Bonnal, Fougere, Serandon, ReStud (1997). Transitions between various states. Piecewise constant baseline hazard and unobserved heterogeneity. Intercept in Table 4, p.702 is baseline hazard near 0. Estimates consistent with A2*

out (Table 2) and with (Table 4) unobserved heterogeneity. Consider estimate in first month. A2* OK.

8. Kennan, JOEC (1985). Strike durations in days. Discrete hazard (logit specification). Probabilities reported in figures 1-6. Probability of settlement is not 0 on first day and this probability is not near 1 (and not the largest).

10. Follain, Ondrich, and Sinha, Journal of Urban Economics (1997). Time to repayment of mortgage in quarters. Meyer type grouped duration data with unobserved heterogeneity. Hazard in first quarter much smaller than in later quarters. Figure 1 suggests that hazard starts at 0. A2* may be problematic.
